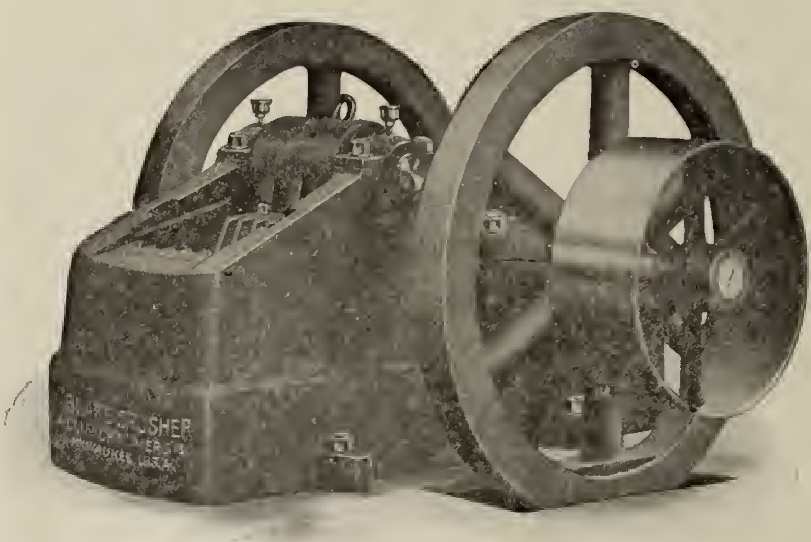
# The "BLAKE" Stone and Ore Crusher

While no form of Jaw Crusher is equal in essential merit to the Gates Gyratory Breaker, there are many conditions that justify the use of the former. This is notably the case when small initial expenditure is an important factor or when a small machine with a large receiving opening is required and great capacity is not essential.



## Improved Style "B" Blake Crusher

| No. | Size or Receiving Capacity | Approx Horse Power Required | Weight Complete |
|---|---|---|---|
| *2 | 10 x 7 | 7 | 6,500 |
| 3 | 15 x 9 | 10 | 12,000 |
| 4 | 20 x 10 | 15 | 15,000 |
| 5 | 24 x 12 | 25 | 25,000 |
| 6 | 30 x 18 | 40 | 47,000 |
| 7 | 36 x 24 | 60 | 80,000 |

*The 10 x 7 Crusher is made in sections, packed in 150 lb. packages as far as possible for transportation in mountainous districts. Weight of heaviest piece 360 lbs.

## Testing for Metallurgical Processes

**By JAMES A. BARR**

216 pages
Illustrated
Indexed

**$2 POSTPAID**

This book is designed to assist in the selection of the process of treatment for any ore. The author describes the apparatus employed in making laboratory and small-lot tests. It is founded upon experimental work at the Michigan College of Mines, and the methods recommended have been tested in practice. It is brief and practical, equally valuable to the student and the practicing engineer.

# Announcement
## of the
# Standard Underground Cable Co., of Canada, Ltd.

WE take this opportunity to wish you a Happy and Prosperous New Year and to thank you for the generous support which you have accorded us during the first eight months of our manufacturing experience in the Dominion, in the shape of substantial orders.

The steady increase and aggregate value of these orders is, we believe, conclusive indorsement of our policy of *high quality* and *fair dealing* which has, for a third of a century, always been associated with "Standard" Products.

We solicit your patronage during 1913 for the following

## "Standard" Products

Wire Rods
Wire and Cable
Standard C. C. C. Wire
(Colonial Copper Clad)
Magnet Wire
Weatherproof Wire
Rubber Insulated Wire
Varnished Cloth Cable
(Varnished Cambric)
Fibre Insulated Leaded Cable

Dry Paper Leaded Cable
Saturated Paper Leaded Cable
Rubber Lead-Covered Cable
Armored Cable
Cable Terminals
"Ozite" Insulating Compounds
Insulating Tape and Sheets
Insulating Varnishes
Cable Hangers and Supports
Cable Installations

Detailed information, samples, estimates or prices cheerfully furnished in regard to any of the products in the above list which is only an outline of our complete list.

Our engineers have had long experience in the installation of cable systems of all kinds and they will gladly advise you regarding your problems in this line.

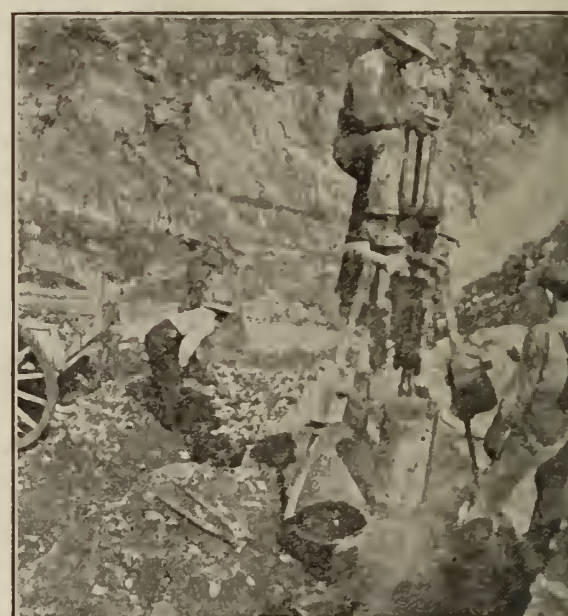
# SIX FEET of SHANKS

## *BROKEN EVERY DAY*

This is the advice of a large mining company who have been using drills with the old-fashioned chuck requiring shanked steels.

### Look at These Resulting Costs:

| | |
|---|---|
| Average length of shank broken - | 6 ins. |
| Number of shanks in 6 feet - - | 12 |
| Cost of the 6 ft. of 1⅛ in. Oct. drill steel wasted 20 lbs. at 7½c. - | $1.50 |
| Time required to re-shank 12 steels: 12 shanks @ 20 min. - 240 min. or 4 hrs. | |
| Labor cost, blacksmith and helper, per hour, - - | 60c. |
| Total labor cost re-shanking 12 drills 4 hours' work, @ 60c. - | $2.40 |
| Total cost of steel wasted - | $1.50 |
| **Total Waste per day -** | **$3.90** |



HOLMAN DRILL ON QUARRY WORK

**HOW LONG WILL YOUR PROFITS STAND THIS WASTE?**

By using the Holman Steel Rock Drill Equipped with its Patent Chuck you need not shank your steel. *Estimate the saving.*

## A HAPPY NEW YEAR

**For our subscribers, our contributors, our advertisers, and for the whole brotherhood of mining we wish a Happy and Prosperious New Year. May every legitimate ambition be fulfilled, may peace reign privately and publicly, and may all and sundry conspire to work out manfully the destiny of Empire and Nation.**

## THE YEAR 1912—A REVIEW

Attempting the role of prophet is dangerous. Twelve months ago, in estimating the probable total value of Canada's mineral output for the year 1911, we exceeded the mark by some millions of dollars. There was, however, some excuse for this. Labour troubles in the West, the re-organization of Amalgamated Asbestos, and other such incidents cut down the gross mineral production.

Despite our previous over-estimate, we venture now to assert that for the year that has just closed there will be recorded a considerably higher total value for the product of mine and smelter. The following paragraph will develop our reasons for so thinking:

**Nova Scotia.**—Once again has our easternmost Province exceeded all previous records in coal production. Actual figures are, of course, not yet available. But the increase has been considerable. The Springhill collieries, under the management of the Dominion Coal Company, have contributed steadily. Both the Dominion Coal Company's and the Nova Scotia Steel & Coal Company's Cape Breton collieries have yielded many thousands of tons more than during 1911. The former company's outputs are greater by at least half a million tons; the latter, by about sixty thousand tons. Except in the case of Springhill, where the output has been brought up by more than one hundred and fifty thousand tons, other changes of figures are mostly light recessions.

While the gold yield has presumably stood still, the fact remains that several important negotiations are pending that will, we hope, do justice to the real possibilities of the Province's extensive and largely improved gold fields.

Gypsum quarrying has been active. There is reason to believe (and here we quote from semi-official advices) that the shipments have been of greater bulk than before.

Manganese mining, though still carried on in a small way, shows signs of strength. Iron ore mining and concentrating have been established and will prosper. Other mineral industries are still awaiting intelligent exploitation.

The iron smelting and steel plants of Nova Scotia have had a good year. New equipment and a strong market have combined to keep up a more than normal pressure. The certain inception of a shipbuilding industry will warrant gradual expansion.

**New Brunswick.**—Only in a mild wiy is New Brunswick a mining Province. The iron property of the Canada Iron Corporation near Bathurst is equipped and producing. Gypsum is quarried in the southern part of the Province. Apart from these two industries the principal activities are the development of the most important gas and oil fields near Moncton, and the projected exploitation of the oil shales in and about the same district. New Brunswick possesses known deposits of antimony, copper, tungsten, gold, and coal. But there has been practically no effort made by the Provincial Government to advertise its resources. The Government includes no organized Department of Mines, and is, apparently, content to drift along, year after year, in stolid indifference to the industry of mining.

. . **Quebec.**—Far otherwise is it with Quebec. The Government of that Province has for some years taken the keenest interest in the industry. The laws have been revised and altered. The prospector has been encouraged, excellent annual reports are issued, and every encouragement is offered to the investor.

Asbestos mining has been placed on a much better footing during the year. In fact it appears probable that this branch of the industry has recovered from its late indisposition. Copper mining, or, rather, the mining of copper-bearing iron pyrites, is progressing. Gold dredging in Beauce county is being actively carried on. Other minor industries, such as the mining or quarrying of magnesite slate, building stones, etc., are in good condition. The past year, indeed, has brought to Quebec a marked measure of prosperity.

**Ontario.**—The outstanding feature of the year in Ontario has been the increasing importance of gold mining in Porcupine. While Cobalt has preserved the even tenor of its way, while the copper-nickel industry at Copper Cliff has flourished and is about to be much enlarged, and while other branches of mining have been active, Porcupine has occupied the centre of the stage. With an output of gold for about six months of the past year approaching two million dollars, the product of less than one hundred stamps, Porcupine is assuredly making good. Before the end of 1913 there will be at least two hundred stamps dropping. It is within limits to estimate the probable output for 1913 at, say, five million dollars. It is impressive and encouraging to know that other camps, Swastika, Michipicoten, Rainy River, and Lake of the Woods, will add considerably to this total.

While Cobalt's production of silver is slightly lower for 1912 than for 1911, the higher price of silver brings the gross value up to a larger figure. The year was marked by several important discoveries, and by great activity in leasing old properties. Gowganda has more than held its own, despite the closing of the Millerett, and there are signs of life in the Elk Lake region.

Whilst it is impracticable here even to mention all the branches of active mining in Ontario, it is well to touch upon certain facts that have changed and improved the position of certain regions. The re-opening of the old Belmont iron mine in Eastern Ontario is at once significant and inspiring. The operating company is a strong Buffalo concern. If success crowns their efforts much good will follow for the whole district. Equally significant is the re-opening of the long-abandoned Cordova gold mine. And here we may remark that it would be well, indeed, if more mining investors took pains to look into the gold regions of Eastern Ontario.

Talc milling has attained the status of an established and growing industry, and the Canadian product has a world-wide market. The mining of iron pyrite is also advancing.

Looking westward, there is tangible evidence of growth in Michipicoten and in other parts.

**Alberta.**—It is most satisfactory to note that the sub-bituminous coal mines have had an exceedingly satisfactory year. So strong has the market been that these collieries have been quite unable to meet the demand for their product.

The danger of a fuel famine seems to be less imminent than before, although the situation is by no means free from adverse possibilities. Lack of transportation facilities is alone responsible for this. The actual coal output of the Province has gone up by leaps and bounds. For the year 1912 it will be practically double the output of 1911.

**British Columbia.**—Like Ontario, British Columbia has experienced a singularly prosperious year in mining. The tonnage of ore mined was much larger than that recorded for 1911, partly on account of the labour troubles of 1911, and partly on account of strong expansion. Copper was produced to the extent of fifty million pounds, as compared with thirty-eight million pounds in 1910. This constitutes a high record. Comparison with 1911 would be meaningless. Gold production was nearly at record figures. The silver yield was the highest in five years. Lead reached the total of thirty-five million tons, closely approximating the yield of 1910, and exceeding that of 1911 by about nine million pounds. During the greater part of the year, no bounty was paid on lead as the London price was above the bounty limit.

The production of zinc and iron was negligible.

Coal outputs were within comparatively few thousands of tons of the highest mark attained.

Taken as a whole, the year was easily the most profitable in the history of the Province. Dividends to the amount of $1,200,000 were paid by metalliferous mines for the first time in some years.

General.

**Technical Education.**—Since the report of the Royal Commission on Technical Education has not yet appeared, there has been little change in the established order of things. Amongst the most important incidents are the extension of the metallurgical department of Toronto University and the completion of the new mineralogical building, Nicol Hall, at Queen's University. The Commission's report is looked forward to with eagerness. It will probably appear early in January of this year.

**Legislation.**—Nothing of importance has been enacted in relation to mining either in the Dominion or the Provincial Legislatures. The draft of a general mining law, drawn up by a committee of the Canadian Mining Institute, is still in "statu quo ante bellum." Nor does there seem to be much hope that Parliament will discuss the matter this winter. Naval affairs will probably cause a pronounced congestion, and other matters will be neglected. Should this be the case, the Dominion Government will have been guilty of an obvious dereliction of duty.

The problem of workingmen's compensation has been discussed and reported upon in Ontario. The labour element has placed itself in an invidious position in its endeavours to organize a superfluous strike in Porcupine. It is a fact, a curious fact, that organized labour takes no steps to remedy evils. This is left to organized capital. The function of labour is apparently the black-mailings of the capitalist after he is committed to definite investment. It is just here that our laws are constructively deficient. If the Conciliation Act means anything it implies that a means is provided whereby differences as between employer and employee may be reconciled without recourse to the crude strike. Of late, the Act has been a dead letter. It has been used only when it suited the purposes of one or of both parties. It has never been a binding obligation upon either. In fact, it has resolved itself into a subterfuge rather than a remedy. That it should be the latter, no one will dispute. The difficulty lies, we think, in inducing employers to present the whole situation completely and sanely. As has been said frequently in these columns, the interests of employer and employee are ultimately identical.

**Departmental.**—In our next issue will appear complete accounts of the work of each Dominion and Provincial Department of Mines for the past year. Here we may be permitted to remark that only Nova Scotia, Quebec, Ontario, and British Columbia have adequate Departments. New Brunswick, Manitoba, Alberta, and Saskatchewan are entirely neglectful of the mining industry.

While the Dominion Government has not yet seen fit to erect a separate Department of Mining, there is hope that this will be done in the near future. The futile policy of tacking mining on to another Department as an adjunct should have been outgrown long ago.

**The Canadian Mining Institute.**—Harmony reigns in the Institute. Possibly too much harmony. We are neither anarchists nor disturbers of the peace. But we are firm believers in the moral value of an occasional disturbance. However, there does not appear to be a cloud of even the size of a man's hand upon the horizon. Yet our trust is in the membership of the Institute. We know perfectly well, that some kicker will arise before the next Annual Meeting. And we will trust to him to make an interesting cloud of dust.

**The Profession.**—A year ago we remarked that Canada had become the "popular hunting-ground for many mining engineers from foreign parts." This is yet true. It is is also true that Montreal, Toronto, Calgary, and Vancouver have had the names of many mining engineers added to their directorate during 1912. The two former cities are liberally supplied with mining talent. Most of the new arrivals, fortunately, have specific connections where with to occupy themselves. Otherwise Canada is hardly a promising field. The consulting engineer, sad to state, has not yet an established hold upon the Canadian public. Time will cure this condition.

**Opportunities.**—In drawing attention to mining opportunities in Canada there is every chance of being over-enthusiastic. Therefore it may be pursuing the safest course merely to point out the fact that in every mining Province, and in many unsuspected regions, there exist excellent chances forthe mining investor. It is necessary, however, to be fully seized of the fact that it requires money to find what is wanted. It is useless, for instance, to begin prospecting unless the prospector is provided with ample means to test his territory. Moreover, it is futile to break into the game at all without having the wherewithal to carry it to a definite conclusion. Foreign investors are singularly obtuse, almost as obtuse as the native variety. But history is being made. Canada is yet in its swaddling clothes as a mining country.

. . . . . .

The year 1913 should be one of monumental progress for the mining industry of Canada. Everything points to continued expansion. The past year has been wonderfully encouraging. This year, we believe, will be even more so.

## EDITORIAL NOTES

Satisfactory preliminary reports from Quebec and British Columbia are printed in this issue of the Canadian Mining Journal. More complete reports from each Province will appear on January 15th.

---

The Hawthorne trial, for which a number of Canadian witnesses have been called, may be brought to a conclusion some time in January. United States procedure is singularly complicated and slow. But the tangled skein is almost straightened out. Many picturesque aspects of the promoting game have been revealed. While it is not yet proper to make final comment, it appears safe to assume that justice will be meted out. Justice Hough, before whom the accused are being tried, is the official who sentenced Morse, the "Ice King," to penitentiary some years ago.

---

Dr. J. Austin Bancroft, of the Geological Department, McGill University, has reported upon the alleged discovery of diamonds near Matagami lake. The blue clays, according to Dr. Bancroft, are merely deposits of aqueous origin, and have not been derived from the communication of basic igneous rocks. He holds out no hope of existence of diamantiferous ground in the region.

---

Erroneous press despatches in connection with the Hawthorne trial have confounded the identities of Dr. Robert Bell, late acting-Director of the Geological Survey, and Mr. J. McIntosh Bell, mining geologist and engineer to Messrs. Ehrlich & Company, London, England. Mr. J. McIntosh Bell had no connection, either directly or indirectly, with the Hawthorne matter.

---

The insinuating oil promoter spares no pains. Not content with ordinary channels, an English firm of alleged bankers, Hatton, Morris & Co., inserts in the November Strand magazine (English edition) a dodger offering free 5 per cent. income certificates and a large amount of cash. The company owns, or pretends to own, 1,300 acres of oil lands. That is the only fact that can be gathered from the dodger. Readers of the Strand are invited to send in their names. "If you receive no reply you will understand that the whole of this wonderful cash and bonus offer has been over applied for." Just so! And the Strand allows its pages to be dirtied with this nonsense!

---

## HOW TO TEST FOR FIREDAMP.

Acting on the recommendation of the chief inspector of mines for the province (Mr. Thomas Graham), Sir Richard McBride, premier and minister of mines for British Columbia, has had distributed among a number of men connected with coal mining in the province a pocket folding card on which has been printed brief instructions "How to Test for Firedamp," as follows:

"To test for firedamp the flame of the ordinary miner's safety lamp must be carefully turned down until only a faint line of blue is seen over the yellow eye or centre, as shown in the illustration.

"The presence of firedamp in the air is indicated by a pale triangular form—common called a 'cap'—which appears over the top of the blue line, varying in size and intensity according to the amount of firedamp. The 'cap' begins to appear when there is about one per cent. of firedamp, and if there is less than two per cent., only the lower part of the 'cap' can be clearly distinguished; but when the amount is about two per cent. the whole of the 'cap,' including the tip, is visible, though, as shown in Fig. 2, it is very faint. The greater the amount of firedamp present, the plainer becomes the 'cap.' With three per cent. (Fig. 4) it is longer as well as more distinct, and with higher percentages the 'cap' extends up into the lamp chimney.

"In testing for small percentages of firedamp, mistakes may easily arise unless the observer makes himself quite familiar with the appearance of the lowered flame as seen in the pure air of an intake road. If there is any petroleum spirit in the oil, particularly if the metal of the lamp is wet with it, a faint 'cap,' called a 'fuel cap' or 'oil cap' is sometimes seen, but by carefully examining the appearance of the lamp in places where the air contains no gas, one can readily learn to distinguish the 'fuel cap' from the 'firedamp cap.'

"If a complete 'cap' (such as is shown in Fig. 2) however faint, is visible on the lowered flame, men should withdraw at once from the working place, and inform the fireman or other official responsible for the ventilation."

The illustrations, which it is not practicable to reproduce here, show clearly the 'cap' mentioned, in several stages. The card is issued by the British Home Office; it can be purchased from Old Country booksellers at the price of three cents.

---

## ELECTRIC SAFETY LAMPS IN COAL MINES.

Both the British and German Governments are offering prizes for miners' electric lamps suitable for practical use and provided with a reliable fire-damp indicator. A condition of the German competition is that both the lamp and the indicator shall be safe in presence of firedamp, even if damaged, and must be capable of continuous service for at least 12 consecutive hours. The lamps must be handy, durable, simple in construction, capable of being securely fastened, easily attended, and economical in use. The indicator must be at least equal to the benzine safety lamp in sensitiveness to methane and foul air. After burning 12 hours, muststill give a light equal to 1 Hefner unit. The prize offered is 25,000 marks.

---

## A FEDERAL MINING LAW.

Dr. R. W. Brock, director of the Geological Survey of Canada, included the following comment on a proposed Federal mining law in the recently-issued "Summary Report" for 1911: "The Canadian Mining Institute for some years has been urging a Federal mining law to govern the acquisition of mining rights on lands under the control of the Dominion Government, on the grounds that the industry has now attained an importance deserving this recognition, and that a law would greatly stimulate the development of the mineral resources on Crown lands. It is also believed that the provinces having control of mining lands will make their mining laws conform closely to the Federal law, and thus secure, throughout the Dominion, uniformity in the mode of dealing with mining rights. At the suggestion of the Government, the Institute formulated the principles upon which it desired the law to be based. Mr. J. M. Clark was engaged to draft an Act based on these principles. Subsequently, Mr. F. T. Congdon and the Director of the Survey, were requested by the Committee on Mining Law of the Institute, to revise this draft. After spending several months on the work they submitted a new draft which, with a few minor changes, has been accepted and recommended to the Government by the Canadian Mining Institute."

# THE MINING INDUSTRY IN THE PROVINCE OF QUEBEC DURING, 1911.

T. C. Denis.*

By far the greater proportion of the mineral production of the Province of Quebec is derived from non-metallic products. In fact, during the year 1911, the metal mines contributed but 3 per cent. to the total yearly mineral production of Quebec. This is very low and liable to give a false impression of the possibilities of our metalliferous resources. This low metallic output is not necessarily a matter for discouragement, for if we consider our sister province Ontario, we see that over 50 per cent. of the value of its total mineral production is extracted from two fields, which are only a few square miles in area, viz., silver from Cobalt, and nickel from Sudbury. In the immense territory which constitutes the province of Quebec, the greater part of which is practically untouched, there are numerous bands of rocks similar to those which have given rise to the celebrated metal mines of Ontario, and the presence of such deposits may be revealed at any time in our province.

According to the Mining Laws of the province of Quebec, the operators of mines and quarries are required to make returns of their production in the first ten days of January of each year. It is, therefore, impossible, at this early date, to give more than surmises as to the mineral production for 1912.

In 1911, the total value of the products of mines and quarries of the province of Quebec amounted to $8,679,786, and from all appearances, there will be a substantial increase in 1912.

After having passed through a rather critical period of two years, owing to over-production and glutting of the market, the asbestos industry is gradually resuming a normal state. At present, there appears to be a greater demand for the long fibre qualities and prices for grades of $60 and over are satisfactory. The prices for lower grades, however, are still below normal, and are not remunerative.

In consequence, only the mines which can produce a certain proportion of good fibre were operated during the year. In Thetford and Black Lake, great activity ruled during all summer and fall, and some difficulty was experienced in getting the necessary labour. All of the East Broughton mines were closed down, as the rock in that field is essentially milling rock and the fibre is short.

In 1911, the shipments of asbestos amounted to a value of over $3,000,000. The shipments of asbestos over the Q.C.R. for the first nine months of 1912 showed an increase in tonnage of some 12½ per cent., as compared with the corresponding period of 1911. From this it may be augured that, in spite of the closing down of the East Broughton mines, the value of the asbestos production for 1912 will be higher than in 1911.

The increase in the price of copper caused a renewal of interest in the Eastern Townships deposits of this metal. However, only two mines shipped ore; the McDonald mine and the Eustis mine.

The McDonald mine at Weedon is operated by the East Canada Smelting Company. It was in very active operation all year. During the early part of the year when the ore had to be teamed six miles to the railway, the shipments were at the rate of 2,000 tons a month. In the spring, this progressive company installed an aerial tramway, four miles long, of a capacity of 200 tons per 10 hours, which decreased the cost of hauling to about one-tenth, and the shipments for the last six months have increased tremendously. The development is kept well ahead of mining and they have a good reserve of ore blocked out.

The ore is a pyritous copper ore, running 40 to 45 per cent. sulphur, and averaging 4 per cent copper, some shoots of ore running much higher. The sulphur contents is used for the manufacture of sulphuric acid and the copper is extracted from the cinders.

The Eustis mine worked without interruption and also greatly benefitted from the improved conditions of the copper market. The ore there is of the same nature as at the McDonald mine, the deposit and mode of occurrence being similar.

It is very likely that the Eustis Mining Company will shortly install an Elmore oil concentrator to relieve their present mill.

Considerable work was carried on in re-opening the old Ives mine and the Huntingdon mine, both on the Eastman branch of the Canadian Pacific Railway. At the Huntingdon, a concentrating mill is being installed. No shipments were made from either of these two mines.

On Calumet Island, work was carried on, interruptedly, re-opening the old lead and zinc mines. A concentrating mill of a capacity of 150 tons a day has been built, but very little has been spent in development proportionately to the cost of surface construction.

At Notre Dame des Anges, in Portneuf county, a great deal of work was done on the lead and zinc deposits mentioned last year. The ore is found in a contact zone of crystalline magnesian limestone, which in places is strongly impregnated with zinc blende and galena. This zone, in places, is quite wide, forty feet or more, and it has been followed by trenching and outcrops for half a mile or more. A concentrating mill was built during the summer, but could not be completed to start operating this year.

The production of gold is still confined to the operations of the Champs d'Or Rigaud-Vaudreuil Company, near Beauceville, and to the gold contents of the pyritous ores of the Sherbrooke district. Although considerably larger than last year, the gold production will not probably be as high as was anticipated. There is no doubt, however, that the alluvial gold industry in Beauce will henceforth grow and improve yearly.

Discoveries of lode gold were reported from Lake Kinawisik, in Northwestern Quebec, in narrow quartz stringers.

No actual mining operations were carried on in the chromite deposits, but the Black Lake Consolidated did some exploratory work and diamond drilling, which are said to have given satisfactory results.

The graphite industry received quite a setback by the closing down of the Dominion Graphite mine and mill, of Buckingham, but this was offset to some extent by the uninterrupted operations of the Bell Graphite Company and by the work of a new company, the Quebec Graphite Company, in which it is said German capital is interested.

*Superintendent of Mines, Mines Branch, Quebec.

**Beauce Hydraulic Co.**

The prices ruling for mica were improved, and it is probable that the shipments will show a substantial increase over last year.

The general development of the province, and the growth of the urban centres will certainly be reflected in the figures of the building materials industry. The demand for building and ornamental stone has been very active. As an instance, two new marble quarries

**Dominion Marble Quarry, South Stukely, Quebec**

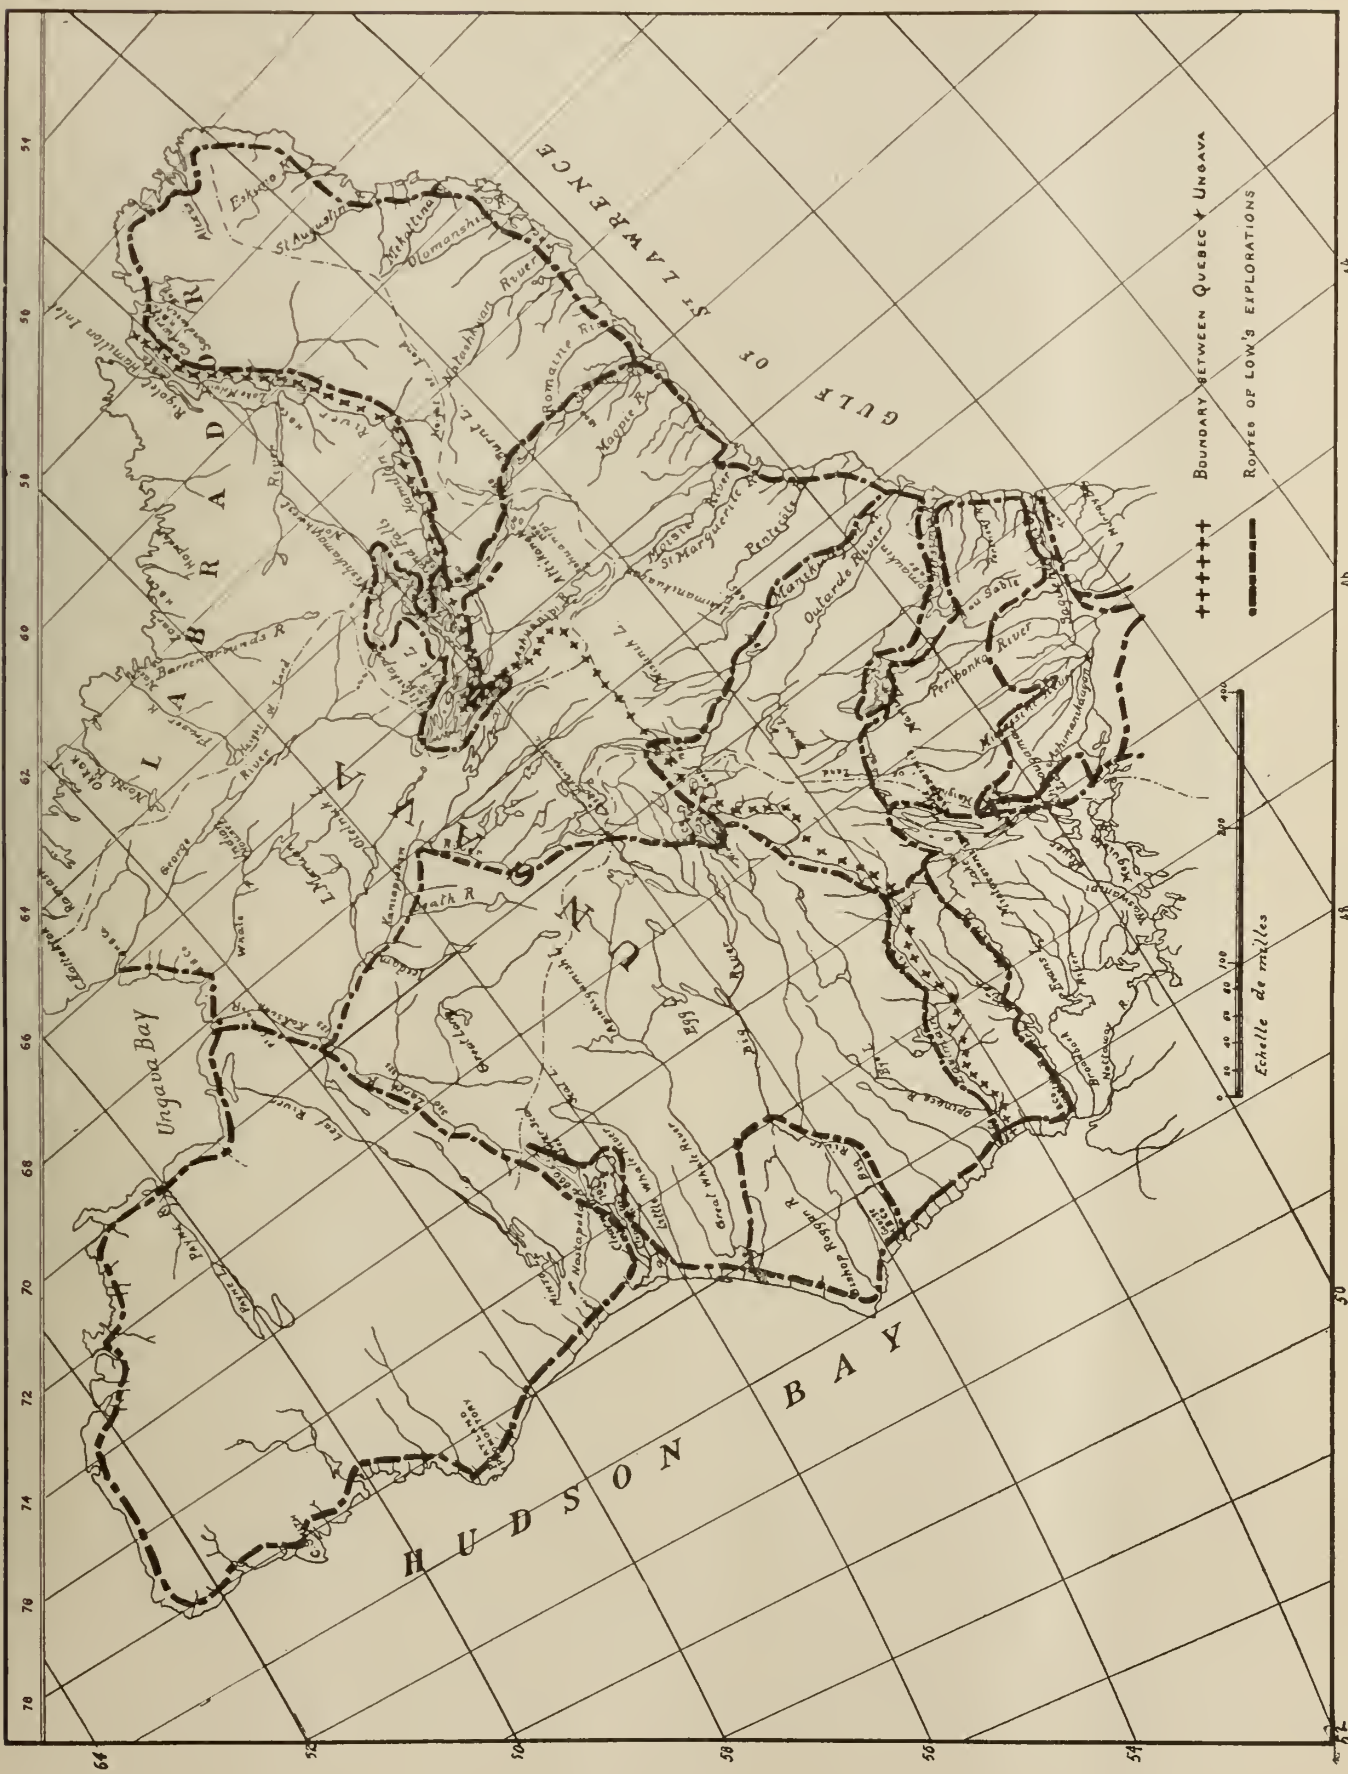
were opened this year and although no shipments from these were made, it is expected that, in 1913, they will be in shape to produce. One of these quarries is situated near Portage du Fort, in the Upper Ottawa region, and the other at St. Theele, Champlain county. Both the Missisquoi Marble Company and the Dominion Marble Company, operating at Phillipsburg and South Stukely, respectively, have had a very successful year. Their products are in every way equal to the best foreign marbles.

The production of peat in the province of Quebec will probably amount to some 2,000 tons. Although small, it is the largest yearly production ever recorded. The Peat Industries, Limited, who have a modern plant installed at Ste. Brigitte, near Farnham, are responsible for the whole production.

**View of Missisquoi Marble Quarry**

In May, 1912, the boundaries of the province of Quebec were extended northward by the annexation of Ungava, and at the last session of the Quebec Legislature, this territory was officially erected under the name of New Quebec. This extension of boundaries more than doubles the area of the province which now embraces a superficies of nearly 707,000 square miles.

This territory is yet very little known. From the ex-



QUEBEC ADDED TERRITORY

plorations which Mr. A. P. Low conducted for several years for the Geological Survey, it would appear to be underlain almost altogether by Archean rocks. The Laurentian formation of gneisses and granites occupy the largest portion of it, but the presence of large tracts of Huronian and Keewatin rocks have been observed and these can be regarded as offering great possibilities from the mineral standpoint.

# MINERAL PRODUCTION OF BRITISH COLUMBIA, 1912.

By E. Jacobs.

A rough estimate of the quantity of ore produced in 1912 places it at 2,600,000 tons, which is 400,000 tons higher than that of 1910, previously the record year. More than two-thirds of this production was from the copper mines of the Granby and British Columbia Copper companies.

In quantities of minerals produced, as compared with 1910 (labor difficulties so interfered with the 1911 production that comparison with that year would not fairly indicate last pear's progress, but show it to too great an advantage) there was an increase in all but gold and coal, and it is probable that revised returns will show a close approach to record figures in these. The chief increase was in copper—a production of approximately 50,000,000 pounds as compared with 38,000,000 pounds in 1910. Of course, the substantial increase in 1912 as compared with 1910 in average price of copper, and in smaller degree of silver, added materially to the year's increase in total value of production.

**Gold.**—Preliminary returns show a smaller production of gold than has been expected, as to both placer and lode gold. The 1911 yield of placer gold was the lowest in seventeen years; while that for 1912 gives an increase of about 3,500 ounces, it is much less than was expected. Atlin district is highest, with an estimated yield of $260,000, and Cariboo next with $200,000. All other parts of the province are put down at $15,000. Revised returns may show higher results in both Atlin and Cariboo. The total value is estimated at $485,000 as against $426,000 in 1911.

Boundary district, including Hedley camp, Similkameen, appears to have made a net increase in lode gold of 15,000 ounces, and Nelson about 3,000 ounces. Rossland production will probably be found to have been about the same as in 1911, while the Coast district is expected to show a decrease. The total production is estimated at 250,000 ounces, as compared with 268,000 in 19100.

**Silver.**—The output of silver, placed at 2,700,000 ounces, is the highest in five years, 1908-1912. Final returns are expected to show a higher total, but available figures suggest the foregoing quantity as a safe estimate. Nearly one-half has come from Ainsworth-Slocan mines, while about 400,000 ounces is from Boundary district mines, in the ores of which both gold and silver are associated with copper, though the last is the chief metal of value. East Kootenay silver production is estimated at between 350,000 and 400,000 ounces, that of Coast mines at rather more than 100,000 ounces, and from Rossland about 90,000 ounces.

**Lead.**—A total of 35,000 pounds of lead seems to be a reasonable estimate. Lead contained in ores received at the Trail smeltery is estimated at about 44,000,000. The estimated production of metallic lead allows for a loss of 20 per cent. in smelting. Nearly one-third of the lead produced was from the Standard mine, Slocan, while the Sullivan, East Kootenay, contributed a similar proportion. The Van-Roi and Rambler-Cariboo, in Slocan district, and the Emerald, in Nelson mining division, were the chief of the smaller producers, which included some 20 mines in all.

Deep development work done at half a dozen Slocan mines that produced litle or no ore in 1912 gives promise of an appreciably large addition to production in 1913. To a smaller extent an increase from mines near Salmo, Nelson division, may be expected, while in the northern country now being opened by completion of part of the Grand Trunk Pacific railway, through Skeena district, developments at several new properties indicate an early commencement of production of silver-lead ores.

During seven months of 1912 the London price for lead was above £18, so no bounty was paid by the Dominion Government in that period under the "Lead Bounty Act." About $65,000 was paid as bounty on lead in ore mined during the first five months of the year. Approximately $700,000 of the original amount of $2,500,000 voted under the "Lead Bounty Act" ten years ago remains unearned. Under the present Act, payment of bounty will "cease and determine on June 30, 1913."

**Copper.**—The year's production of copper, placed at 500,000,000 pounds, is without question the largest in any year in the history of copper mining in the province. Comparison with the records of 1908 and 1909 will not correctly show the increase in actual production, for some earlier figures represent the copper contents of the ore, while those for 1912 give the estimate of copper recovered.

A glance at the figures of the few larger mines will show that the above-given estimate is well based. For instance, Granby Company's ore output was more than 1,200,000 tons; at 18 pounds of copper to a ton recovered, 22,000,000 pounds is accounted for. British Columbia Copper Company (including New Dominion) mines made an output of about 620,000 tons of ore; at only 16 pounds of copper to the ton, approximately 10,000,000 pounds is also accounted for. Coast mines are officially stated to have recovered fully 15,500,000 lbs., while Rossland mines are credited with 2,500,000 pounds. At 16 cents a pounds (the average will be a fraction higher), the value of the year's output is within the mark at $8,000,000, which for actual production of copper, constitutes a record year for this metal.

**Zinc and Iron.**—An estimate of the crude zinc ore shipped gives a total of less than 3,000 tons, and of silver-zinc concentrate between 5,000 and 6,000 tons. The chief shipping mines are all situated in Slocan district; crude ore was shipped from the Lucky Jim and Noble Five, and concentrate from the Standard and Van-Roi. Beer, Sondheimer & Company, with works at Bartlesville, Oklahoma, through their agent, Mr. J. L. Retallack, have purchased the zinc output of the Standard, Van-Roi, Hewitt (Silverton Mines, Limited), and Monarch.

The French process for the reduction of lead-zinc ores, concerning which much was heard about a year ago, has not yet been advanced beyond the experimental stage.

While the development of deposits of iron ore on Vancouver island has continued, there was little, if any, production of iron in the province in a commercial way.

**Coal and Coke.**—The total production of coal was approximately 3,040,000 long tons gross or, deducting that made into coke, about 2,645,000 tons. The highest previous year's output was in 1910 with 3,139,000 tons gross and 2,800,000 tons net. The output of coke was 263,000 tons, with a single exception,( that of 271,000 tons in 1908), the greatest quantity yet produced in the province in one year. Labour troubles at two of the Vancouver island collieries interfered somewhat with production otherwise the total would easily have been higher than that of any other year. Vancouver island mines produced about 1,553,000 long tons of coal, gross; Nicola valley and Similkameen 191,500 and Crow's Nest Pass 1,296,000 tons. All the coke was produced in the Crow's Nest district, Southeast Kootenay. Three new mines are being opened on Vancouver island.

The new field—Groundhog—in which anthracite coal is stated to occur, situated in the northern Skeena country, was further explored, but it is without transportation facilities, so no production was made there.

**Miscellaneous.**—Platinum in Nelson mining division appears to still be a "will o' the wisp." No important progress has been made towards commercial production of this mineral. Gypsum deposits are being utilized. The demand for Portland cement has been in excess of existing manufacturing facilities in the province, so much has been imported. Output of building stone, clay products, etc., was larger than in any earlier year.

**General.**—On the whole, the year was the best in the history of mining in the province, and the outlook is for still further improvement. For the first time for a number of years companies operating metalliferous mines in British Columbia paid dividends aggregating nearly $1,200,000. These were the Hedley Gold Mining Company, Consolidated Mining & Smelting Company, Standard Silver-Lead Mining Company, British Columbia Copper Company, and Le Roi No. 2, Limited. In addition, the Granby Company made nearly $1,500,000 net profit in 1912. Important development work is being done and mine equipment is now such that increased production is confidently looked for.

### Metallurgical Notes.

The quantity of ore and concentrate smelted at the Consolidated Mining & Smelting Company's works at Trail was between 300,000 and 320,000 tons, which was less than in the fiscal year to June 30, 1910 (487,000 tons) also than in the next following fiscal year (389,000 tons). The decrease was caused by the loss of the Snowshoe ore, of which there was 268,000 tons received in the two fiscal years just quoted. Improvements included an addition to flue chamber, to secure better results in settling of flue dust from copper ores; rebuilding of matte-handling plant, method of treating low-grade matte having been changed; alteration to lead-sampling plant, made necessary by increase in quantity of coarse lead ore received; more electrolytic tanks in lead refinery, to provide for larger output of refined lead; and numerous other changes, chiefly to facilitate handling materials. Experiments in reduction of zinc-lead ores were carried out, but no provision was made for production of spelter on a commercial scale.

The chief change at the Granby Consolidated M. S. & P. Company's smeltery was in the substitution of water-granulation blast furnace slag for dumping it molten. By a system of conveying belts operated by electric motors, the dewatered slag is conveyed up a long incline to a height of 120 feet and then discharged, this arrangement providing room for all slag that will be made here for six or seven years. The quantity of Granby mines ore treated at these works in 1912 was more than 1,200,000 tons. One notable feature of the year's work was that the full battery of eight blast furnaces was operated all the year, one run having been for 156 or 157 consecutive days—from June 5 to November 9—without interruption. The Granby company is purchasing materials and plant and other equipment for a 2,000-ton smeltery, hydro-electric power station, railway, shipping dock, etc., at Granby bay Observatory inlet where its new copper mine is being developed with much assurance of large productiveness.

The British Columbia Copper Company operated its smeltery throughout the year. Ore receipts totalled between 650,000 and 700,000 tons. Much efficiency was secured, monthly totals of ore smelted having ranged up to as high as 65,000 tons, with three furnaces in blast. The greater part of the ores smelted came from the Mother Lode and Rawhide mines. There is in the company's Lone Star mine a large quantity of ore available, but owing to its high silica content concentration tests have been carried out with the object of determining how best to eliminate the excess of silica. This problem is now in a fair way towards being successfully solved.

Most of the copper ore and concentrate shipped from Coast district mines was treated at the smelting works at Tacoma, Washington. This includes the comparatively large output from the Britannia mine.

**Gold Milling.**—The largest stamp mill in operation in 1912 was that of the Hedley Gold Mining Company, at Hedley, Similkameen, at which about 70,000 tons of ore was crushed, as compared with 58,000 tons in 1911. Approximate value of gold recovered in 1912 was $760,000, as against $680,000 in 1911.

There were three stamp mills in operation in Nelson mining division in 1912. No information has been received concerning the Granite-Poorman and Queen mills, but the Motherlode Sheep Creek Mining Company's mill was worked during the latter half of the year. A new installation was that of a 10-stamp mill at the Inland Empire mine, west of Rossland camp. The Jewel 15-stamp mill was also running late in the year.

**Lead and Zinc Ore Concentration.**—The mills that made the largest output from concentration of lead and zinc ores were those of the Standard, Van-Roi, and Bluebell mines, respectively. The Rambler-Cariboo mill was started in December. The expectation is that in 1913 there will be several other concentrators in operation, with a proportionately increased output of both silver-lead and silver-zinc concentrates.

# THE PRODUCTION OF AVAILABLE POTASH FROM THE NATURAL SILICITES.*

By Allerton S. Cushman, Ph.D., Member of the Institute, and George W. Coggeshall, Washington, D.C.

The great demand which has recently arisen for an American supply of potash in available form for agriculture has stimulated not only the search for new sources of this material, but also experiments of a large and practical scale of operation, in the attempt to develop a method of making the vast supply of potash locked up in feldspars and feldspathic rocks either directly water-soluble or sufficiently soluble in dilute acids to insure a product which shall be useful as a fertilizer. The natural silicites commercially available as sources of potash are chiefly orthoclase and leucite. Both of these minerals are potassium-aluminum silicates. The theoretical formula for orthoclase is written $K_2O.Al_2O_36SiO_2$, and for leucite $K_2O.Al_2O_3.4SiO_2$. The principal sodium feldspar albite has the theoretical formula: $Na_2O.Al_2O_36SiO_2$. It is well known that these feldspars run into and substitute each other in various proportions, so that the products from different quarries will vary widely in respect to their soda and potash contents. There is an enormous supply of feldspar in the United States, both East and West, which could be made economicaly possible as a source of potash supply, provided the cost of production can be made low enough to compete with the potash-holding manure salts which are at present so largely imported from Germany. Although it must be admitted that the imported potash salts are richer in potash than any product that can ever be made from American feldspars, it should also remembered that the crude German manure salts contain large quantities of chloride and sulphates of elements which are not only undesirable in the fertilizer, but which may do actual harm under certain conditions. It is this fact which gives encouragement to the attempt to produce from American feldspars a straight potash fertilizer which could be used in exactly the same way that hardwood ashes have been found useful.

Six general methods have been proposed for decomposing the natural silicates, in the effort to obtain water-soluble potash salts.

### I. Adaptation of Natural Agencies.

In the processes of Nature, the slow action of moisture and atmospheric agencies, including the action of carbonic acid gas, is known to have a decomposing or kaolinizing action upon the feldspars. Immense deposits of feldspar and granitic rocks have thus been decomposed, with the formation of large beds of kaolin and clays from which the potash has been leached into the surrounding valley. For this reason, the valleys between feldspathic and granitic hills are usually highly productive of the crops which require large amounts of potash, such as tobacco, potatoes, large fruits, berries, etc. There have been a few processes proposed, which depend principally upon the natural reactions hastened by pressure and other agencies. In 1904, Blackmore (U.S. patent 772,206) proposed the action of carbon dioxide gas under five hundred pounds pressure upon a cream of the ground mineral, repeated intermittently for several hours, in the attempt to produce a yield of carbonate of potash. Ten years earlier the same experimenter (U. S. patent 513,001) had proposed using lime, calcium chloride, and steam pressure in an autoclave to produce chloride. In 1910, Coate (U.S. patent 947,795) proposed the addition of bacteria for the decomposition of feldspar. In 1910, Carpenter (U.S. patent 59,841) proposed to heat the mineral intensely and cool suddenly by plunging in water. in the effort to render the feldspar amporhous, in the hope of making it more available for plant growth. None of the above processes have as yet been shown to possess industrial possibilities.

### II. Wet Processes of a Chemical Nature.

Levi, in 1904 (French patent 344,246 and English patent 13,875), and Piva, in 1905 (French patent 351,-338), proposed methods ofr treating leucite by means of solutions of alkali or alkali earth hydrates, generally under increased pressure. The same general method for treating feldspar was claimed by Swayze in 1907 (U.S. patent 862,676) and by Giggs in 1906 (U.S. patent 910,662).

Also, Gibbs, in 1904 (U.S. patents 772,612 and 772,657), proposed a process of treatment with hydrofluosilicic acid, and subsequently with sulphuric acid, in order to produce potassium sulphate. In 1907, Cushman was granted U.S. patent 851,922, a public patent which proposed the sludging of finely-ground feldspar with water, the addition of a small amount of hydrofluoric acid, and electrolyzing the mixture in wooden cells provided with wooden diaphragms. Under this process both potassium and aluminum hydrate passed through the cell diaphragm into the cathode compartment. This process, although perfectly practical, has not yet been made commercially possible, owing to the high cost of hydrofluoric acid and the large amount of by-products formed in the process. None of the above processes have as yet been made commercial possibilities.

### III. Dry Processes of a Chemical Nature, in which the Potash Salts are Volatilized.

In processes of this nature, fluxes, and in some cases fuel, for reducing purposes are ground and mixed with the feldspar, the mixture being subsequently heated until the potash salts are volatilized and collected either in the stack dust or partially collected from the gases by passing them through or over water. Swayze, in 1905 (U.S. patent 789,074), heated ground feldspar with gypsum and carbon, and proposed to collect the volatilized sulphate. Spencer and Eckel, in 1909 (U.S. patent 912,266), made a cement mixed with calcareous and silicious fluxes and green sand, a natural potash-bearing iron silicate, clinkered the mixture in a rotary cement furnace, and obtained a Portland cement, at the same time collecting the potash in the stack dust and the flue gases. In 1911, Eckel (U.S. patent 1,011,-172) proposed a somewhat similar method, but heated only high enough to drive off the potash salts and not high enough to clinker the mixture. Again, in 1911, Eckel (U.S. patent 1,011,173) melted a mixture of green sand, limestone, and fuel, tapped off the melted iron and slag and recovered the potash salts from the flue gases.

Some of the processes under this heading have been tried on a large scale. No great difficulty is recorded in driving off the potash in the furnaces, but obstacles were encountered in the attempt to collect the potash from the gases. As a by-product operation in the

*Paper read at the Eighth International Congress of Applied Chemistry.

manufacture of cement, these processes may yet come to be of some industrial importance.

### IV. Dry Processes which Propose to Separate Potash as Hydroxide or Carbonate.

The old method of Bickell, proposed in 1856 (U.S. patent 16,111), which depended upon heating a mixture of feldspar, lime, and natural phosphate rock or guano to a bright red heat, has not as yet been proved practical or successful. The process of the Soc. Romana Solfati, in 1905 (French patent 352,275), which proposes the roasting of leucite with carbonate, hydrate, or nitrate of soda and lime, and subsequently the passage of steam through the roasted product to produce sodium aluminate and potassium carbonate, is possible from a chemical standpoint, but the high cost of operation has not permitted the process to come into commercial use.

### V. Dry Processes Producing the Chloride.

In 1900, Rhodin (U.S. patent 641,406) and in 1901 (J. Soc. Chem. Indus., xx., 439) proposed fritting feldspar with lime and salt. According to the published results, this experimenter obtained good yields, although the process has not become a commercial success. In 1907, McKee (U.S. patent 869,011) suggested heating a potash-bearing material containing mica with lime, salt, and carbon in order to obtain a yield of potassium chloride. Cushman, in 1911 (U.S. patent 987,436), proposed mixing feldspar with lime and salts of a mineral acid capable of decomposing the silicate, giving the mixture special treatment previous to heating in a rotary furnace in order to produce the chloride. This method has been tried out on a large mill scale of operation, and the results obtained will be discussed later on in this paper.

### VI. Dry Processes Producing Sulphates.

In 1911, Thompson (U.S. patent 995,105) proposed heating to a bright red heat mixture of feldspar, sodium acid sulphate, and sodium chloride, and subsequently leaching out the potassium sulphate produced. This experimenter claims that potassium chloride is first formed, which is subsequently changed to the sulphate by the action of the acid sulphate. It is stated that this process has recently been tried on a commercial scale of operation. Sodium acid sulphate is a by-product that is reasonably cheap, although a large quantity is not available. The lack of an abundnt supply of acid sulphite is perhps the greatest drawback to the commercializing on a large scale of this process, although it is possible that it may still become of some industrial importance. Hart, in 1911 (U.S. patent 997,671), proposed to fuse faldspar with some barium compound, such as the sulphate, together with carbon, to pulverize the cool melt, and subsequently to digest the product with sulphuric acid and thus produce in solution potash alum and a residue of barium sulphate and silica which is claimed to be useful as a paint pigment. Hart claims that some of the potash is volatilized during fusion. Since the fusion temperature is 1,500 deg. C., it is probable that a considerable portion of the potash does volatilize, and it is possible that this dufficulty may interfere with the commercial success of the process.

Wadman, in 1907 (U.S. patent 847,856), proposed heating lepidolite with potassium sulphate and leaching the product with sulphuric acid in order to obtain sulphates of lithium and potash.

A chronological list of the patents which have been granted for the treatment of the silicates for the production of available potash is given in Table. I.

It would appear that the most promising processes for making potash available from the natural silicates on a commercial scale of operation are those which are conducted in the dry way but without actual fusion of the reacting mixture. Potash salts volatilize readily at the high temperatures necessary for the fusion of the silicates, and the collection of the volatilized potash from the stack gas has not yet been carried out eco-

TABLE I.

**Proposed Extraction Processes Chronologically Arranged.**

| | Patentee. | Year. | Process. | Product. |
|---|---|---|---|---|
| IV | Bicknell | 1856 | Lime, $ca_3(PO_4)_2$ red heat | Caustic. |
| I | Blackmore | 1894 | Lime, powdered $CaCl_2$, $H_2O$, steam | KCl. |
| V | Rhodin | 1900 | Lime, salt, heat under melting | KCl. |
| II | Levi (leucite) | 1904 | $Ca(OH_2)$ or NaOH pressure 16 atmosphere | K silicate. |
| 11 | Gibbs | 1904 | $H_2siF_6$ and $H_2SO_4$ | $K_2SO_4$. |
| I | Blackmore | 1904 | $CO_2$ 500 pounds pressure repeating | $K_2CO_3$. |
| II | Piva | 1905 | (Leucite) K.O.H, NaOH, steam 25 atmospheres | K silicate. K aluminate |
| IV | Coe. Romana Solfati | 1905 | (Lucite) alkali, carbon, Ca.O red heat... heat | $K_2CO_3$. $K_2SO_4$. |
| III | Swayze | 1905 | Gypsum and carbon, fuse, volatilize | $K_2SO_4$. |
| VI | Wadman | 1907 | Lepidolite, $K_2SO_4$ $H_2SO_4$ | $K_2SO_4$. |
| II | Cushman | 1907 | Water and HFl electrolysis | K.O.H. |
| II | Swayze | 1907 | Heat alone, then KOH solution | K silicate. |
| V | McKee | 1907 | "Containing mica" with CaO, NaCl, and C. | K aluminate KCl. |
| II | Gibbs | 1909 | $Ca(OH)_2$, steam 150 pounds | K.O.H. |
| III | Spencer and Eckel | 1909 | Green sand cement, mix, volatilize | K salts. |
| I | Coates | 1910 | Bacterial action | |
| I | Carpenter | 1910 | Intense heat, sudden cooling down | |
| V | Cushman | 1911 | CaO, $CaCl_2$, etc., clumps, red heat | KCl. |
| VI | Thompson | 1911 | $NaHSO_4$, NaCl, bright red | $K_2SO_4$. |
| VI | Hart | 1911 | Ba compound as $BaSO_4$ and C, fuse, $H_2SO_4$ | Alum. |
| III | Eckel | 1911 | Cement mix but not over 900° C. with green sand volatilize. | $K_2O$. $K_2SO_4$. |
| III | Eckel | 1911 | Green sand, $CaCO_3$ and C. melt iron volatilize. | $K_2SO_4$. |

nomically. A considerable portion of the potash does not settle in the dust chamber, and if water sprays are used for washing the gases the potash solutions are very dilute and the cost of evaporation becomes prohibitive. Furthermore, water sprays are found to interfere with the draft regulation, even when the use of fans is resorted to. The maintenance of artificial draft is an expensive and difficult matter, and is very likely to infere with the proper control of the furnace temperatures. For work on the large scale of mill operation, a continuous process must be used, avoiding fusion and with the regulation of temperature to the exact point at which appreciable quantities of potash do not volatilize. The fluxes and reacting substances must be cheap, available in large quantity, and the yields of water-soluble potash salts must be high. The process which has seemed to us to give the most promise of successful adaptation to commercial ends is that of Cushman (U.S. patent 987,436), coupled with the method of preparation of the materials before furnacing, proposed and developed by Coggeshall (U.S. patent 987,554).

This process has recently been given extensive trials on a large scale and interesting results have been obtained. The process consists essentially in powdering 100 parts of potash feldspar rock, together with about 20 parts of lime and with or without 10 to 20 parts of rock salt. This powdered mixture is fed to the top of a moving drum about three feet in diameter, in a layer about half an inch deep. As soon as the layer is formed a strong solution of calcium chloride is applied from a series of small tubes. The $CaCl_2$ at once unites with the lime, forming a so-called oxychloride cement, and a large portion of the mixed powder is thereby at once formed into "clumps" or aggregates lying in a bed of surplus powder. As the drum revolves the bed is removed by a scraper to a belt which delivers the mixture to a screen which separates the clumps from the residual powder. The powder is returned by a screw conveyor and elevator to the hopper above the drum again. The clumps are about the size of peas and pass from the screen directly to a rotary kiln similar to those used in burning Portland cement. The kiln is heated by a blast of air and powdered coal in the usual manner.

The clumps pass regularly down through the increasingly heated portions of the rotating kiln and roll out at the end, practically without alteration in size and shape.

A large percentage of the total potash present in the feldspar is converted into potassium chloride during the heat treatment, and very little is volatilized. The dry clumps are of a pale-yellow color outside, due to the iron in the ash of the bituminous coal used, but they are snow-white inside. The clumps are finally ground, producing a pale-yellow material containing as much water-soluble $K_2O$ as hardwood ashes, although the potash is in the form of chloride and the product also contains considerable free lime. Up to the present time no attempt has been made on a large scale to leach out the soluble potash. The ground material is being given field tests as a straight potash fertilizer containing lime.

### A Resume of the Large Scale Experiments.

Potash feldspars were obtained from five different localities. Eleven carloads were used in the trials, amounting to a total of 385 tons. Each carload was ground and analyzed separately. The lowest in potash ran 6 per cent. $K_2O$ and 3 per cent. $Na_2O$, the highest 11.3 per cent. $K_2O$ and 3.1 per cent. $Na_2O$; the bulk of the spar 10 per cent. potash and 2 per cent. soda, and the results given in this paper were obtained on the 10 per cent. spar.

The lime was a high calcium quick-lime, running about 90 per cent. CaO and 5.6 per cent. MgO.

The salt was rock salt from New York State and ran about 98 per cent. NaCl.

The calcium chloride was obtained from the Solvay Process Company. It was in the solid form and contained about 75 per cent. $CaCl_2$ and 25 per cent. water.

All of the above materials are available in very large quantities and at low cost. The calcium chloride is a by-product in the form of a moderately strong solution, and but a small proportion is concentrated at the present time, as the chief use is for refrigeration purposes. Vast quantities are now run to waste. The solid form was used in these trials merely for convenience.

Many heats were made with mixtures of varying proportions, but the two mixtures used in the work here described were:

| | | | |
|---|---|---|---|
| Feldspar ......... | 100 | Feldspar ......... | 100 |
| Lime ............. | 20 | Lime ............. | 20 |
| Salt .............. | 10 | Salt .............. | 20 |

The feldspar, lime, and salt were separately crushed in gyratory crushers and rolls, and dried in a rotary drier. In continuous work the proper mixture would be made at this point by continuous weighing machines, but as a number of different mixtures were to be tried, each of the three raw materials was ground separately in Huntington mills and put into the bins. This preliminary grinding of the feldspar and salt was to about 65 per cent. through a 100-mesh sieve, of the lime about 83 per cent. through the 100-mesh. The weight per cubic foot of each powder of the above fineness was then ascertained, and measuring boxes were built so that the materials could be separately measured out and run together into a large mixing machine. Almost a ton was thus mixed each time. The mixture was then conveyed to a tube-mill and further ground to a fineness of from 97 per cent. to 99.5 per cent. through a 100-mesh sieve, and then conveyed to the bin over the clumper and kiln.

The calcium chloride masses were broken up and thrown on a perforated grid in a large tank holding about 48 tons. Water was run in and the chloride dissolved most readily. The solution was run out when about 42 deg. Beaume into two large sump tanks, and brought to a constant strength of about 42 per cent. $CaCl_2$. This was then pumped up to an elevated tank and piped from there through a constant-level tank to the dropper tubes of the clumper placed in a row above the drum. This drum is 15.5 feet long and 3 feet in diameter, and is horizontal. There are 15 valved pipes, each one feeding an adjustable pipe holding 38 short dropping tubes of brass 1/16-inch internal diameter and set 5/16-inch apart.

The finely-ground, mixed powder is taken from the bin by a chute, elevator, and screw conveyor and distributed in a long hopper trough over the drum. It is taken from the trough by a roll device and spread evenly on the moving drum at its topmost point. The drum has a surface velocity of about 1.6 inches per second, the layer of powder advancing at this rate.

It was found that by dropping the liquid very rapidly upon the powder the clumps could be made rapidly enough to give a full fed to the short rotary kiln when only one-third of the trough and droppers and drum is used. A clumper drum 5 feet long produces every hour almost two tons of fresh clumps and considerably over a ton and a half of burned product with the kiln used in these trials. The excess of powder passes through a screen and goes to the same elevator which lifts the original material from the bin. The amount of actual $CaCl_2$ in the fresh lime is regulated to about 20 parts to each 100 parts of feldspar in the mixture. The clumps leave the screen in rounded form and flow directly into the kiln.

The reason for the above procedure will now be explained. In the first place, calcium chloride reacts very efficiently under these conditions with the feldspar by replacing the potassium with calcium, thus forming calcium silicate and potassium chloride. Anhydrous calcium chloride is expensive to produce, and it is impracticable to grind it into a mixture on a large scale on account of the rapid absorption of moisture. Even if such a dry mixture could easily be made, its use would present certain disadvantages

When a reaction between an ore and solid fluxes is produced by heating up to the fusing temperature, the reaction takes place on the surface of the particles alone and only at the points where the ore is in actual contact with the flux particles. Finer grinding will produce a larger surface area and thus a greater number of actual contact points, leading to a larger yield. There is, however, a degree of fineness beyond which it is not wise to go on account of the cost of extremely fine grinding.

Another factor in the problem is brought out by the following experiments. A batch of ore and the theoretical amount of solid flux were ground together to just pass a 50-mesh sieve. This powder, when subjected to a certain heat treatment, gave a reaction yield of about 35 per cent. of the theoretical. The mixture was then ground to just pass a 100-mesh sieve and given the same heat treatment. A reaction yield was obtained of about 65 per cent. of the theoretical. The mixture was then ground to pass a 200-mesh sieve and again reheated as before. A smaller yield was obtained than when the material just passed the 100-mesh, although the particles were undoubtedly only half the average diameter with about four times the surface area and should, therefore, have had far more points of contact. Upon weighing equal volumes of the 50-mesh, 100-mesh, and 200-mesh powders, it was found that the latter contained far less material, and it became apparent that the 200-mesh powder consisted for over 54 per cent. of its volume simply of voids. Such finely-ground powders are well known to "surge"—that is, to show the tendency to flow like water through orifices in a manner resembling fountains. Material ground as fine as this is the cause of much trouble at spout slides and conveyors. Each particle of a material of this extreme fineness is undoubtedly surrounded by a film of air, the actual contact with the surface is lessened and friction almost eliminated. When allowed to flow into a bin, such a powder assumes an almost horizontal surface; there is practically no angle of repose. Unquestionably the lessened contact caused the low yields in the finely-ground mixtures. Some of the finer material was briquetted and the subsequent heat yield about 85 per cent. of the theoretical. Briquetting is, however, expensive and usually necessitates the addition of a binding agent foreign to the reaction.

As a result of these investigations, the method was developed for aggregating fine powders by dropping a suitable liquid upon an excess of the powder in such a way as to cause a temporary bond to form, thus practically eliminating the air films or voids around the individual particles and permitting actual surface contact. Under these conditions, with the same ore and flux used in the experiments described above, the same heat treatment yielded within 3 per cent. of the theoretical quantity present. This method of aggregating finely-powdered materials previous to furnacing has already been used in several different ways. For example, in an ore mixture in which the fluxing material is an alkaline carbonate, such as sodium or potassium, which forms crystalline salts containing water of crystallization, if the carbonate is used in the partially anhydrous condition and ground with the ore water alone dropped upon the mix in the manner described formed at once a crystalline carbonate which binds the particles of ore and flux into separate clumps, which are hard enough to withstand screening, while the air films are practically eliminated. Using such a mixture and process as this, a practically theoretical yield was obtained, although the flux was used only in the exact molecular proportion called for by the reaction.

By this clumping process a very intimate contact of reaction of surfaces is readily obtained at a low cost. The quantity of flux necessary to complete the reaction is greatly reduced, the duration and temperature of the heat treatment is lessened, and, working with rotary kilns, dusting and stack losses are almost entirely eliminated. The clumps are beautifully adapted to the feed mechanism of rotary kilns, as they flow easily, do not dust, and take the heat more evenly than fine powders. Now that the temperature conditions in rotary kilns can be accurately controlled, it would seem that many chemical and metallurgical reactions which are now performed by intermittent processes and with low yields could be much more economically carried out in continuous rotary kilns, taking advantage of this new method of forming aggregates previous to furnacing.

In the application of this method to the treatment of feldspathic rock, advantage was taken of the fact that a solution of calcium chloride acts upon dehydrated lime to form the oxychloride, which is a strong cementing compound. It was found that the formation of calcium oxychloride gave a sufficiently strong bond to enable the aggregates to withstand the operation of screening and the burden in the kiln.

The theoretical quantity of calium chloride flux required depends upon the total quantity of $K_2O$ and $Na_2O$ present in the mix, as it is evident that the soda must also be liberated in proportion to its content. The feldspar ore used ran 10 per cent. $K_2O$ and 2 per cent. $Na_2O$, which required theoretically 15.5 parts of calcic chloride.* In all our trials some slight excess of calcium chloride has been used. The strength of the solution and the method of treatment have been such that about 20 parts of actual calcium chloride are present in the fresh clumps to every 100 parts of feldspar. The 20 parts of lime used are for the purpose of forming the aggregates, and this lime remains practically unchanged in the finished product. The presence of lime in a potash fertilizer will be found advantageous to most soils, and it is generally admited that lime increases the manurial value of a fertilizer. If the object was to leach out the soluble potash salts from the product, a much smaller amount of lime could be used without interfering with the formation of hard clumps. The salt is added because it has been found to aid the heat reaction, probably mechanically, as will be explained later on. The fresh clumps contain from 16 to 20 per cent. of moisture, which is, of course, evaporated in the upper part of the kiln.

The rotary kiln used in these trials was one of the old bottle shape cement kilns with a total length of slightly over fifty-five feet, the upper twenty feet having a diameter of 4 feet clear inside the firebrick lining, the lower portion widening out to nearly 6 feet inside diameter. The pitch was ⅞-inch per foot, and the most suitable speed was found to be one revolution in about 2½ minutes.

The conditions of the heat treatment are very important. The kiln used was too short to yield the best results, and after the preliminary experiments changes were made which caused the material to take about $1\frac{1}{2}$ hours to pass through the length of the kiln. The temperature of the gases issuing from the upper end of the kiln were read continually with a thermo-couple pyrometer fitted with a 15-foot fire end, and temperatures were also taken from time to time at the firing platform. A furnace wall temperature of about 1370 deg. C. is required for efficient burning of powdered bituminous coal. This is, however, much too high a temperature for potash work in a rotary kiln. This difficulty called for careful experimental investigations and adjustments of the heat treatment before the proper yields could be obtained. If a longer kiln had been available, there is every reason to believe that a more efficient use of the heat could have been obtained. The coal used was a fairly high volatile bituminous coal. It was ground to about 94 per cent. through a 100-mesh sieve and blown into the furnace under an air pressure of about ten pounds per square inch.

During the progress of the clumps down the kiln the following reactions probably take place: At the entrance to the kiln the water begins to evaporate. As the hotter zone is approached, the temperature rises high enough to melt calcium chloride and salt. Whether the calcium chloride is free to melt is not known to us, as the exact composition of the oxychloride compound formed has not yet been determined. The results of our work seem to prove that the reacting chlorine is more readily evolved from the oxychloride compound than it is from calcium chloride alone. The melting of the salt, however, continues the bond of the reacting particles, causing them to thoroughly "wet" each other, and from this point on the attack on the silicate proceeds rapidly. During the heating usually from 1 to 2 per cent. of $Na_2O$ is volatilized.

When operating with no salt present, the yield of soluble potassium chloride was 47.5 per cent. of that originally present in the feldspar. On adding to the mixture 10 parts of salt to each 100 of spar, a test heat yielded 64 per cent., but of this 9 per cent. was lost by volatilization, giving a yield of 55 per cent. net in the final product. On adding 20 parts of salt to the mixture the yield grows to 69.2 per cent. with no volatilization and to 75 per cent. under heat conditions which caused a volatilization of 7 per cent., leaving a net yield of 68 per cent. of that originally present. In the case of clumps made from a mixture of 100 parts of feldspar containing 10 per cent. $K_2O$ and 2 per cent. $Na_2O$, 20 parts of lime, 20 parts of salt, and 20 parts of calcium chloride, the theoretical composition if no volatilization loss takes place is shown compared with the actual results obtained in the following table:

| | Theory. | Analysis. | |
|---|---|---|---|
| Total $K_2O$ | 6.25% | 5.8% | |
| Water-soluble $K_2O$ | ...... | 4.2% | Equals 6.65% KCl. |
| Loss of $K_2O$ | ...... | .5% | As KCl already formed. |
| Total $Na_2O$ | 7.62% | 7.1% | 52% made into NaCl. |
| Water-soluble $Na_2O$ | 6.37% | 5.1% | Showing 1.79% vaporized as NaCl or 26% of that present. |

This particular product contained 11.2 per cent. of free lime, and total lime by analysis 15.5 per cent. There was also in this sample about 5 per cent. of free unchanged calcic chloride. The amount of calcic chloride in the various runs made up to the present time has been reduced gradually to about 1 per cent., and it is felt that in the future better conditions of heat treatment will make complete use of the calcic chloride and at the same time raise the yields of soluble potash. In later runs, in which only 10 parts of salt were present in the mix, the theoretical and actual analysis of the product was as follows:

| | Theory. | Analysis. | |
|---|---|---|---|
| Total $K_2O$ | 6.66% | 5.62% | |
| Water-soluble $K_2O$ | ...... | 4.5 % | Equals 7.12% KCl. |
| Vaporization loss of soluble $K_2O$ | ...... | 1.04% | As KCl already formed. |
| $K_2O$ insoluble in water | ...... | 1.12% | |
| Total $Na_2O$ | 4.15% | | |
| Water-soluble $Na_2O$ | ...... | 3.7 % | Showing 0.45% vaporized as NaCl or 11% of that present. |

This product contained 12.25 per cent. of free lime, the total potash rendered soluble was 5.45 per cent. of the product or 83.2 per cent. of the total quantity present, but as 15.6 per cent. had been volatilized the net yield in the product amounted to 57.6 per cent.

The material which was later made continuously according to the process described above carries 4.5 per cent. of water-soluble $K_2O$ in the form of 7.12 per cent. potassium chloride, and in addition to this material carries only 1.12 per cent. $K_2O$ insoluble in water. It is well known that a 2 per cent. citric acid solution will extract, when used according to the Wagner method, somewhat more $K_2O$ than can be made directly water-soluble. This fact is of considerable interest when the product is to be used directly as a potash fertilizer.

## Conclusion.

It is believed that under better conditions of heat treatment which can be obtained with longer kilns and with a somewhat different arrangement of the combustion chamber, slightly better yields than those reported can be obtained. It should be remembered that the kiln used in these experimental trials was originally designed for burning cement, but this type of kiln has long been superseded by improved forms. In order to get the proper heat treatment in the middle of the kiln to complete the reaction, it was necessary to have the upper part too hot. This condition will not maintain in a properly-designed kiln. It is also believed that the use of oil as fuel would have allowed an easier regulation of the heat treatment, but the trials so far undertaken have been made conditions which were found available at the time.

The subject of the costs of this process and of the product cannot be gone into in detail at this time, but a few general statements may be made. The production of water-soluble potash in feldspathic work is essentially a low-grade proposition, and the commercial success of such a process depends upon the low cost of the various operations. The manufacture of a straight potash fertilizer containing as valuable ingredients only potash and lime must be carried out on a very large scale and by the most modern methods of continuous operation. With regard to the clumping process, the trials have shown that this operation can be practically carried out as a continuous process and at an exceedingly low charge per ton of product.

The process may be directly compared with that of the manufacture of Portland cement. It is little easier to grind feldspar and lime than the shales and limestones used in cement manufacture. Drying will cost no more. Chemical control of the raw mixes will not be more expensive, and perhaps much less. Clumping, as has been shown, adds a very small charge to the expense of treatment. The cost of furnacing the feldspar mix will be less than similar charges in the cement industry, as the temperatures required are much lower and less coal is consumed. The product from the potash kiln is comparatively soft and pulverizes easily in hammer mills, while the charges on the cement industry for grinding clinker are an important item. Again, the softer potash product merely requires to be ground fine enough for use as a fertilizer, whereas cement clinker must be ground very fine and costs rise rapidly with increasing fineness. Repair bills in the case of feldspar treatment should be much smaller than in cement manufacture. The charge for raw materials is somewhat larger than in the case of cement, but this is more than met by the smaller costs of operation.

The potash fertilizer as now produced should be the equal in fertilizing value of the ordinary grades of hardwood ashes. The product carries practically the same content of water-soluble potash and somewhat more lime than wood ashes. There is every reason to believe that if the process becomes an industry the yields of water-soluble potash can be considerably improved. The material yielded is not a fused product; it is friable as an ash and it has the physical texture to make it a valuable aid to soil structure. The success of the product must, of course, depend upon the results obtained under test conditions in its experimental use as a fertilizer. If results are obtained which are as good as, or better than, those which usually attend the proper use of high-grade wood ashes, it is believed that there should be no reason why this product cannot be successfully produced and introduced, especially in those parts of the country where potash feldspars, fuel, and shipping facilities are available.

### Summary.

In this paper a summary is given of the various processes which have been proposed for making the potash in the natural silicates available as a fertilizer.

Experimental trials of a new rotary kiln process for treating feldspar are described, which depends upon a previous treatment before furnacing, consisting of a method of aggregating or clumping the mix so that chemical contact of the reacting substances is brought about during the subsequent processing. The qualitative and quantitative results obtained on a number of experimental trials on a mill scale of operation are presented and discussed. It is shown that it is possible to economically manufacture a potash fertilizer containing free lime from feldspar, and for a sufficiently low cost to make an industry based upon the method worthy of consideration.

# MINING PROSPECTS.

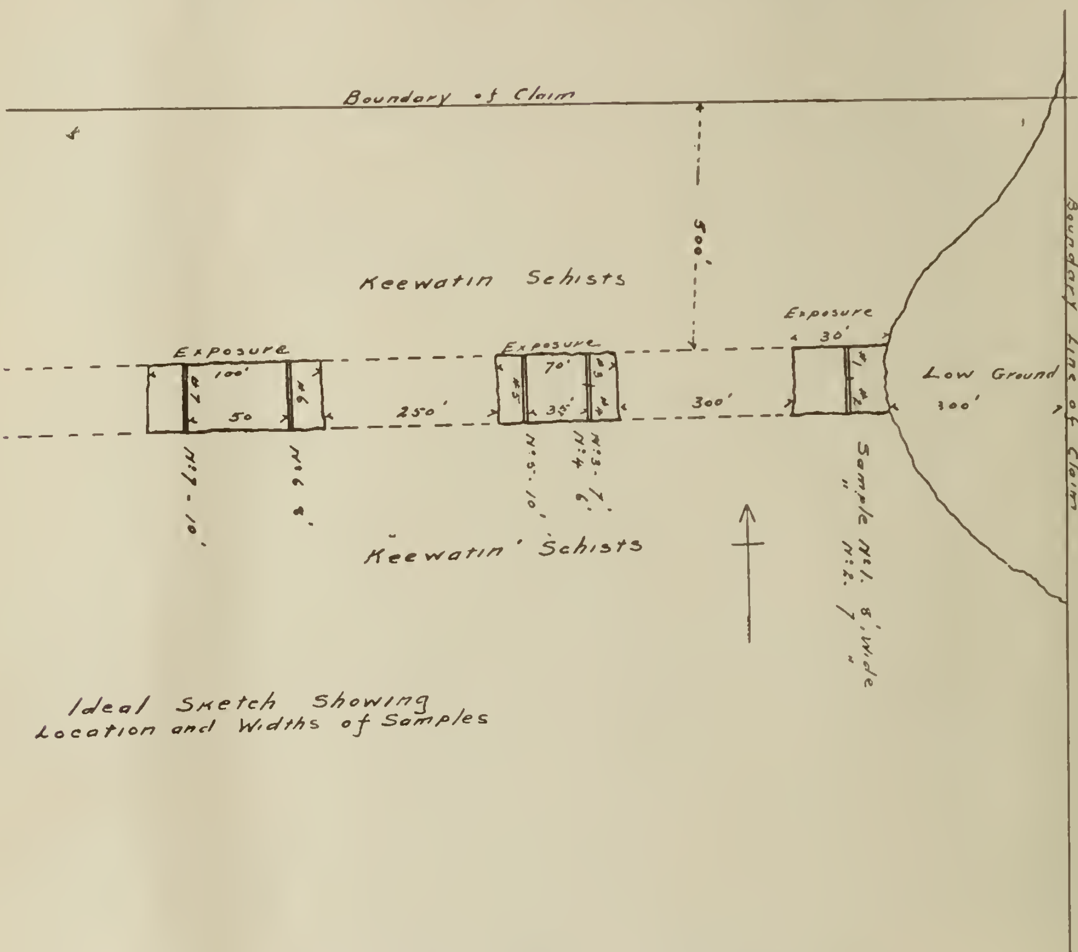
(Written for the Canadian Mining Journal by an Examining Engineer)

The examination of a prospect is one of the most difficult things that the average engineer has to undertake, as in many cases it calls for more qualifications than the examination of a developed or partially developed mine. The information available is usually so meagre that it is often extremely difficult to decide whether or not a property warrants the expenditure of money. In submitting a prospect for consideration it is, therefore, essential that the owner of the property gives as much information as possible. All engineers, and particularly those associated with development or exploration companies, have many prospects presented to them, and, in the majority of instances, they are not given any consideration on account of insufficient detail. Examinations of prospects are usually attended by considerable discomfort and expense and engineers are loth to undertake them without something definite to go on. In many cases, promising prospects are allowed to lie undeveloped because the owner has not taken sufficient trouble to present his property in proper form.

The usual method of procedure is to send a few selected specimens, accompanied by a glowing description of mineral wealth which only needs development to bring in immense fortune to the person lucky enough to acquire the property. Incidentally the owner usually asks an extremely high price and a substantial payment down. Selected specimens, are, however, of little value to the engineer and have a tendency to mislead him instead of giving valuable information. The writer recalls one instance in particular where the owners brought in some rich specimens of free gold, claiming that the vein averaged six feet in width, that it could be traced for a long distance, and that the lowest assay ever obtained was $6.00. The examination necessitated a two days' trip into the bush under most disagreeable conditions, and when the property was finally reached, it was found that the vein would not average more than fifteen inches in width and that the specimens brought to the office accounted for practically all the free gold there was. Outside of this single showing of gold, the highest assay from sections across every part of the vein was 80 cents.

In order to properly present his property, the owner should send as complete a description as possible. The accessibility of the property, together with the general geological features should be stated, and particular pains should be taken to give clearly, the character and average width of the vein, the distance over which it can be traced, the number of exposures, and how far these have been stripped and how far apart. Samples from the various outcrops should also be sent. These samples can very easily be cut with a small prospector's pick and a moil and should weigh approximately two or three pounds per lineal foot of trench. The width of the samples should be carefully measured and each sample should be put in a separate sack with a separate number and sent to the engineer, accompanied by a sketch, no matter how rough, showing the location and width of each sample, and the distance apart of the different sections. Where a vein is much over ten feet wide, it is usually advisable to split the samples, taking not more than ten feet for each. In this way, the location of a possible pay streak can be determined, and it might show a profitable section of ore, which, over a greater width, would be unprofitable.

The work outlined above can be done by any man having a very slight knowledge of mining, and while, of course, an engineer would not purchase a claim on these results, it would enable him to obtain a fairly comprehensive idea of the width and assay value of the ore and would certainly entitle the seller to much more consideration than he would otherwise be likely to obtain.



Ideal Sketch Showing Location and Widths of Samples

# TECHNICAL LITERATURE.

**The Relation of the Horse-Power to the Kilowatt.**—Prior to 1911, no precise definition of the horse power that was generally accepted and authorative, was current; and different equivalents of this unit in watts, are found in text books. The most frequently used equivalent in watts, both in the United States and in England, has been the round number 746 watts. The United States Bureau of Standards has issued a circular in which it is pointed out that it is obviously desirable that a unit of power should not vary from place to place, and the horse power thus defined as a fixed number of watts does indeed represent the same rate of work at all places. Inasmuch as the "pound" weight, as a unit of force, varies in value as g the acceleration of gravity varies, the number with the latitude and altitude. It is equal to 550-foot pounds per second at 50 degrees latitude and sea-level, approximately the location of London, where the original experiments were made by James Watt to determine the magnitude of the horse power. The "continental horse power," which is used on the continent of Europe differs from the English and American horse power by more than 1 per cent., its usual equivalent in watts being 736. These values, 746 and 736 watts, were adopted as early as 1873 by a committee of the British Association for the Advancement of Science. The value, 0.746 kilowatt will be used in future publications of the Bureau of Standards as the exact equivalent of the English and American horse power. Both the Bureau and the Standards Committee of the American Institute of Electrical Engineers recommend the kilowatt for use generally instead of the horse power as the unit of power.

**Dredging in the Yukon.**—Dr. H. M. Payne describes, in the Engineering and Mining Journal of December 14th, the present method of dredging on Bonanza creek, the results of which, we understand, have during the past season, proved very gratifying. Here, whenever practicable, the dredging of the creek bottom precedes the hydraulicing in order to avoid handling the hydraulic tailings through the dredge, although in some instances it has been found profitable to wash these tailings again through the dredges. The gold-bearing gravel and overlying muck being frozen, it is first thawed by driving steam points down to bedrock. The points are spaced at intervals of from 8 to 10 feet, and driven from 5 to 30 feet down, depending on the depth of the frozen overburden. Steam is generated by portable boilers and transmitted through a main 3-in. pipe to 2-in. headers and 1½-in. goosenecks, with which the points are connected by rubber hose. These points are in varying lengths, like drill sets, and are advanced as thawing takes place by men standing on step ladders and wielding sledge hamers. It is aimed to thaw several weeks' in advance of the dredges in order that the ground may "sweat," and thus thoroughly disintegrate the frozen mass, the black muck on the surface acting as an insulator and retaining the heat introduced through the points. The dredges are of the regular type, with buckets averaging 7 cubit feet capacity, and a chain speed of 18 buckets per minute, giving a theoretical capacity of 6,720 cubic yards per 24 hours.

**Asbestos in West Australia.**—The Geological Survey of West Australia has issued recently a report by Mr. Torrington Blatchford on the asbestos deposits at Soanesville, in the Pilbarra goldfield. The rocks here are serpentine, which has been intruded by dolerite dykes. Asbestos has been found in several places within the area, but only two exposures have been prospected to any extent. Locally, these deposits are known as the "A" and "B" lodies. In the "A" deposit the fibre is short, and fit only for mill treatment. On the "B" lode, which has been developed to a depth of 149 feet, some very fine asbestos has been exposed, the fibre being in places several inches in length and of exceptional quality, but apparently the deposit is very narrow. The author thus concludes his report: "Up to the present the boundaries of the serpentine rock are hidden by the Nullagine series of altered sediments. This is unfortunate, as there should be more possibility of finding large formations of asbestos near the boundaries of the serpentine than anywhere else. . . . The total cost of producing the marketable product at Pilbarra aud pntting it on a local or foreign market, including labour of mining, cobbing and bagging, transport, etc., would probably not exceed £20 per ton. There is, therefore, a good margin of profit in working good crude fibre. In estimating the value of milling fibre, the difficulties are many. If the average price of all grades of mill fibre be taken, the Canadian price is £6 per ton. Taking the asbestos veins as they stand exposed in the workings, and after making due allowance for high mining costs under existing conditions, it would cost at least 20s. per ton to mine and mill the asbestos rock on the spot. If the percentage of recoverable fibre and milling rock be twenty, this would mean a cost of £5 to produce one ton o fmill fibre, exclusive of cartage, freight, realization charges, etc." The shipments of asbestos so far made represent 40 tons, valued at $1,600, sold in 1908, and 283 tons, valued at £154 sold in 1909.

**The Care of Wire Rope.**—A writer in the Engineering and Mining World remarks that the life of a rope is materially reduced if made to work round small drums and pulleys. When considering the size of pulleys for underground haulage, convenience of handling is the important factor, and, therefore, the ratio usually observed between the size of a winding rope and its pulleys is much reduced. For underground haulage a satisfactory workable minimum diameter for a sheave or pulley is 60 times the diameter of the rope. Thus a three-quarter inch rope would require a pulley 3 feet 9 inches in diameter. If the pulley is larger the rope is so much the better for it, but if made smaller it is done at the risk of injuring the rope, unless it be of special construction. A high speed of rope means a considerable amount of wear, and it is better to increase the load than the speed. Jerking is ruinous to ropes, and a careless engineman may easily, by picking up his load rashly, snap even a new rope. Ropes before use should be stored in a dry place, upon timbers; and if left a long time, oiled over occasionally. Where they are not galvanized ample protection should be afforded by a suitable oil, free from any ingredient that might set up corrosion. Hoisting ropes are usually well served in this respect, while haulage ropes are just as much neglected. The following test shows the importance of greasing ropes: Two lengths of rope, same size, same make, one oiled the other unoiled. The latter made 16,000 bends, and the former 38,700 bends over the same pulley before breaking. Again, similar pieces were tested over a 24-inch pulley. The unoiled stood 74,000 bends and the oiled 386,000 bends before breaking.

**The Dry Cleaning of Coal.**—The Mining and Scientific Press comments recently on a process for the dry cleaning of coal in use in Franklin county, Irrinois. The coal is first carefully sized on a series of gyratory screens, and then by a spiral separator which makes three products: coal, bone coal, and slate. The spiral separator consists of a centre column, with a series of spinal bands, down which the coal and slate slide. The coal maintains a fixed path as long as the friction of the coal on the chute and the centrifugal force balance. As the velocity increases, to where it overcomes the friction, the coal moves over the outer edge of the spiral plate and is carried off through a hopper. The slate, with a higher co-efficient of friction, follows the regular path down the spiral and at the bottom goes into the refuse pocket. The bone coal takes a path between the two and slides to the outer edge of the spiral, but does not follow the coal over the edge. It is delivered at the bottom through a special gate, and may then be conveyed to the boiler house.

**Electrolytic Extraction of Copper.**—The United States Consul at Christiania reports that for several months past a company at Aamdal, Norway, has been extracting copper successfully from the crude ore by means of an electrolytic process invented by Victor Hybinete, a Norwegian engineer. The treatment, which is done at the mine, thereby effecting considerable economies in shipping costs, consists in leaching the crushed ore with a solution of sulphuric acid which dissolves out the copper; a strong current of electricity is then passed through this solution and the pure copper is precipitated. Experiments on copper pyrites, elsewhere in Norway, have proved equally successful.

**A New Nickel Extraction Process.**—The Engineering and Mining Journal describes a new process for which a patent has been granted to Horace L. Wells, of New Haven, Conn., for the extraction of nickel from nickel-copper matte by means of hydrochloric acid. The matte is pulverized to 60-mesh, or finer, and treated with 18 to 25 per cent. hydrochloric acid at a temperature between 110 and 212 F. The first solution is then decanted or filtered off, and the residue is again treated with further amounts of acid. This is done because one treatment will not extract all the nickel, no matter how long continued or how strong the acid. The acid used in the second treatment is not exhausted and is available for use as the first leach in treating a succeeding batch of nickel matte. The matte is agitated during this treatment. The solution of nickel chloride thus obtained is treated for nickel or for nickel salt, as provided for in the various other patents of T. C. King and H. L. Wells.

**The Study of Earthquakes in Germany.**—The Colliery Guardian calls attention to a recent description of the appliances used in the magnetic observatory and earthquake station connected with the Bergewerkschaft at Bochum. The object of the station is to observe and to record the phenomena of natural and "artificial" earthquakes and to study them in their bearing upon mining. The Bergewerkschaftkasse, it may be mentioned, is a common fund to which all the mine proprietors of the district have to contribute. Prof. Heise is the director of the schools. The equipment consists of three astatic Wiechert pendulums, two suspended so as to record the horizontal components, and one for registering the vertical component. There are also two portable horizontal pendulums, each for two components, of the Rebeur type, for recording gradual changes and inclinations and depressions caused by excavations in mines. The third set of instruments comprises two highly sensitive portable seismometers for photographic records, the one a horizontal pendulum of the Weichert-Mintrop type, the other a universal pendulum of Dr. Mintrop. The records are produced in kinematograph fashion. With these instruments the movements of the ground are being observed continuously at Bochum.

# METHODS OF PROSPECTING AND DEVELOPING DEPOSITS IN MICHIGAN.

By R. E. Hore.

The method of prospecting in the copper country is now in almost all cases diamond drilling and trenching. The outcrops have long since been carefully looked over, but there still remains to be prospected a very extensive area, which is covered with glacial debris. The most notable new discoveries during the past few years have been made by drilling in such covered areas.

Exploration is also carried on underground at several mines. It is usual near an important lode to find parallel lodes which are not regular enough to be worked alone, but which carry at intervals copper in quantities sufficient to pay for extraction. In some mines prospecting for such deposits is carried on by systematic drilling into the foot or hanging from the workings on the main lode. In others, cross-cuts are driven at less frequent intervals for the same purpose. In mines where a filling system is used, the rock cuts into hanging and foot are run far enough to explore other lodes.

In putting down the first drill hole in an exploratory campaign in drift covered areas it is the usual practice to set the drill at an angle normal to the dip as determined on neighbouring properties. If the hole proves to be approximately normal to the bedding, other holes are bored at such distances that each will give a slight overlap over the section obtained in the next one. Many of the holes are drilled 1,000 feet to 2,000 feet. Where there is little known concerning the stratigraphy, the most satisfactory results are often obtained by vertical holes.

The cores drawn are closely examined for copper; and also for the purpose of correlating the various strata cut. Commonly all the core is kept regularly arranged in boxes. At intervals in the core-box a mark is made to indicate the depth from which the core was taken. After examination the cores are usually stored and kept for future reference.

**Development.**—When a lode has been located, development is usually begun by sinking an inclined shaft in the lode or in the foot-wall. Exploration is carried on by drifts at levels about 100 feet apart. As a rule it has been found advisable in running these drifts, to follow the hanging or the foot-wall rather than to take straight courses. On the Calumet conglomerate the drifts are on the foot, but on most of the amygdaloid lodes the hanging wall is followed. This practice enables the miner to keep to a definite horizon, as the contact of the hanging wall trap with the lode is usually rather distinctly marked. Moreover, a bed that is cupriferous usually shows most regular ore shoots close to the hanging, so in keeping to the hanging the miner is, most of the time at least, following the ore. In a few mines the hanging is not very closely followed, but this is largely because in these mines the contact is not easily recognized. In another mine thousands of feet of drifts run in regular courses in the copper-bearing bed disclosed very little ore, while subsequent drifts following the hanging proved up very large deposits. The wisdom of keeping to the hanging was early recognized, and with a few exceptions the best results are still obtained in this way. There are some cases, however, in which it is perhaps just as well to follow the foot. In wide lodes there is usually much copper close to the foot, as well as close to the hanging. If then, the foot-wall is more easily identified than the hanging, as sometimes though rarely happens, it may be preferable to follow the foot. In the conglomerate mines the foot is followed because it presents a good fact to draw the cut to, rather than on account of the values there. As a rule drifts run without following closely the foot or hanging, soon get away from the ore, and are of comparatively little use in estimating the value of the deposit. There are, however, a few cases where the broken nature of the ground makes it practically impossible to follow foot or hanging closely, and then courses are run along the strike of the bed.

When it is desired to explore at depth the underlay of a lode productive on adjoining property, vertical shafts, are sunk and at various levels cross-cuts run into the lode, which is then developed in the usual way. At some mines similar "deep' ore is reached by starting the shaft down at an angle of about 80 degrees and curving at depth into the dip of the lode.

There are in Houghton county three vertical shafts that are very nearly one mile in depth, and several shafts on the slope of the lodes that are down over one mile on the incline. The deepest vertical shaft is 5,308.5 feet and the longest inclined shaft is 7,995 feet measured on the dip.

The ore cannot be satisfactorily sampled in the mine. After considerable ground is blocked out it is tested by a mill run extending over a few months. The usual practice is to rent a stamp at one of the mills and test the ore thoroughly before erecting a new stamp mill.

**Methods of Mining.**

As all the deposits being worked are in the form of inclined beds there is a marked uniformity in the way in which the lodes have been opened up. The method of mining the ore, however, is by no means the same for all the mines. The method adopted depends chiefly on the geological conditions, especially on the dip and thickness of the deposit and firmness of the lode and wall rocks. As a rule the copper deposits are in unusually uniform and firm rock that is easily supported. There are, however, some mines in which the lode or hanging wall is full of seams and joints, and the necessity of providing support has then then made it advisable to use a different method of mining. The greatest similarity in methods is found in mines working the same lode.

There are also, however, notable differences in method which do not result from the geological conditions, and which may be seen on the same lode and often in the same mine. Very often stoping has been started near the shafts and advanced toward the boundary, while in other cases stoping has been begun at the boundary and advanced to the shaft pillar. The latter makes less support necessary, thus making it possible to allow the ground to cave soon after a stope is cleaned out, and at the same time renders protection for levels necessary only under the one stope being worked.

In some mines drifts are run of ordinary size 7 feet by 7 feet, while in others the opening is carried forward as a drift stope, by cutting the full width of the lode and taking a few cuts off the back. The drift stope method gives a better opportunity to follow sinuosities of a lode closely, thus making possible a more definite estimate of its contents; but unless the lode is very uniform in grade there is likely to be broken rock that might be better left standing. In long drifts the better ventilation in the large opening is a decided advantage.

In wide lodes the ores is not as a rule evenly distributed, and a considerable percentage of the lode is worthless. There is then to be decided whether it is better to break the full width of the lode and sort out the waste, or to make the selection before breaking, and as far as possible leave the poor rock standing. The mines on one lode use the former method, while on another wide lode the latter system is utilized.

Methods of handling the ore differ largely according to the nature of the deposit and also for other reasons. In some mines mechanical scrapers are used in stopes, while hand shovels are used in others under similar conditions. In one mine chutes are used to load tramcars, while in another mine where the dip of the lode is practically the same, the ore is allowed to run down to the track level and then is shoveled up into the cars. In most mines the men themselves push the tramcars, while in others rope haulage or electric locomotives are used. In most mines the ore is dumped directly from tramcar into skip, while in a few, ore pockets are used. In most of the mines ore is hoisted from every level; but in some the ore from four or five levels is run down in chutes and hoisted from one level.

The methods of mining in use will be best understood from brief descriptions of the practices in individual mines. The variations dependent on the nature of particular deposits will be brought out by taking as examples mines that are on different lodes. For the conglomerate lode we can take the workings tributary to one shaft at the Calumet and Hecla mine; for an amygdaloid 14 feet thick and with dip of 40 degrees; for a narrow amygdaloid at a steeper angle (45 degrees), the Hancock; for deeper workings on a narrow amygdaloid dip 38 degrees to 45 degrees, the Quincy; and for a wide amygdaloid of steep dip (73 degrees), the Baltic.

**The Calumet and Hecla Mining Method.**—The Calumet and Hecla conglomerate is now being mined at great depth from several shafts, one of which is vertical and the others inclined. The lode averages 15 feet in thickness, and dips usually at an angle of between 37 degrees and 38 degrees.

The incline shafts are sunk in the lode, and levels established at intervals of about 100 feet. Drifts 8 feet by 8 feet are run each way from the shafts to the boundary. A raise is put through for ventilating, and to provide a stoping face, and stoping is begun first at the boundary. A cutting out stope is run for 100 feet by cutting a slice off the back for the full width of the lode. Then heavy timbers are put in to support the hanging and protect the level. No square sets are used. Heavy timber is placed as stulls, three large sticks being placed close together and forming a so-called battery. Batteries of stulls are placed about eight feet apart, leaving a space of about five feet. In this space a chute is built at sufficient height to deliver the ore into tramcars. Above the chute the foot is covered with an iron plate 8 feet by 4 feet to enable the ore to run readily.

When stulls and chutes are in place heavy lagging is placed across the stulls, planks are placed over the timbers for the drillers, and regular stoping is commenced by breast cuts taking off 8 feet to 12 feet at a time. In each 100-foot stope two or three drills work a short distance apart. As each cut is taken off the back, additional stulls are placed in line above the others. The broken ore falls down between the rows of stulls, and with some assistance from shovellers runs down to the chute and is loaded into tramcars. As the process goes on the ore is replaced by regularly spaced rows of stulls up to within a short distance of the next level. Stoping is carried on until all the ore is broken, no pillars being left anywhere in the stope. There are no arch pillars to support the levels above. The whole section of the lode is broken and swept down between the rows of stulls into the tramcars, mechanical scrapers being used to drag the ore down.

When the stope has been cleaned out, a solid row of heavy stulls is set across the foot of the stope, a considerable portion of the timber in the stope being robbed. The stope is then allowed to cave, the car-tracks are taken up, and the thoroughly worked out part of the mine immediately abandoned. The 100-foot block next towards the shaft is then attacked in the same way, and at the same time in the next lower level, stoping is begun at the boundary. Stoping is always done at several successive levels at the same time, and in any one level stoping is always being done in a block 100 feet nearer the shaft than the work in the next lower level. At the shaft a pillar 100 feet wide is left on each side.

To work out a stope takes about eight months. Hence, stulls across the foot of the stope, while necessarily heavy, do not need to be of long-lived wood. Consequently the heavy stulls are not of very valuable wood; but of timber common in the district—hemlock, birch and maple being generally used. The hardwood is used green and does not last long after it dries. Sometimes before a stope is worked out, caving starts in the level above, and small quantities of rock fall down onto the row of stulls. No damage is done, as the timber is still strong and the amount of caving slight. In a year or two the timbers have become weak, but by this time there are no miners in the stope below. At intervals there occur caves in the hanging and ultimately the stope is filled with the broken rock.

There is no sorting of the broken ore in the mine. Sometimes blocks of poor ground are left standing; but everything broken is hoisted. The tramcars are pulled to the shaft by air-engine rope haulage, and the ore emptied directly into skips. A seven ton skip makes seven or eight trips an hour to surface from a depth of 7,000 feet. At surface a little rock is picked out, as the ore is fed to the crushers.

**The Wolverine[3] Mining Method.**—The Wolverine mine works a section of the Kearsage lode, which here dips at an angle of 40.5 degrees to 41.5 degrees and averages 14 feet in thickness. Shafts are sunk in the foot-wall and levels established at intervals of about 100 feet. Drifts are carried forward as drift stopes. The drift itself is about 6 by 7 feet and the lode is cut out for its full thickness for a distance of 19 feet from the foot rail. When the drift stope has been advanced a few hundred feet a block of ground 75 feet long is marked off, and this is stoped out by four men on contract. The whole block is drilled by only one machine. A block is stoped out in about four months. The first block being raise and stope requires several weeks longer.

Owing to the dip there is no difficulty in rigging up drills on the foot, and at the same time the inclination is sufficient to allow all but the finest ore to run down to the level. No protection at the level is necessary, and no timber is used in the stopes. Rock pillars are left along the foot of the stope and a 8-foot to 10-foot floor pillar in the back. The ore runs onto a sollar beside the track, and is shovelled up into the cars. At the Mohawk mine where similar methods are used, the dip is in places not sufficient for the ore to run, and iron chutes are used in cleaning the stopes. A large number of cars are used at each level, and the trammers leave their loaded cars at the shaft. A special crew of workmen load all the ore into the skip, working their way down from level to level, and then riding up and going over the ground again.

**Hancock Mining Method.**—At the Hancock mine is illustrated an economical method of mining a narrow lode dipping at an angle of about 45 degrees. In mining this lode use is made of a vertical shaft which is being sunk to open up the Pewabic lode at greater depth. In early workings an inclined shaft was sunk to the thirteenth level and three lodes opened up. The present method is in use below the thirteenth level on No. 3 lode.

A winze was sunk in the lode for about five hundred feet, and the lode worked from levels about 100 feet apart. At the eighteenth level connection was made with the vertical shaft by a long cross-cut. The winze was then no longer used for hoisting, but was converted into a chute, and all ore from upper levels brought down to this level.

Drifts are run 6 feet by 7 feet. A cutting out stope follows enlarging the opening to 24 feet. A row of stulls 4 feet to 6 feet apart is set above the level and lagged over with cedar poles 4 inches to 6 inches diameter. At intervals of about 25 feet a hole 2 feet by 4 feet is left in the lagging, and a high sollar built about 4 feet above the car rails. When the level is thus protected and provision made for handling the ore, stoping is commenced. In the first cut care is taken not to shoot the rock directly against the timbers. After a few feet of broken ore lies on the lagging, the remainder of the ore can be broken with wet holes. Enough ore is left in the stopes to support the miners and the rest drawn off. The ground is firm and no timber is used in the stopes. Rock pillars are left where poor rock is found, and an arch pillar, 6 to 10 feet thick, is left in the back of the stope to support the level above. The ore is drawn out of the stopes onto the sollars and there sorted and loaded into tramcars. The cars are pushed by hand to the converted winze, which is now a chute having two compartments, one for ore and one for rock. At the bottom of the chute the ore is loaded into saddle-back tramcars, each holding about three tons, and drawn by electric locomotive to the vertical shaft. Here the cars are run over bins into which their contents are emptied. From the bin the rock is let into the skip by raising a heavy gate, and dropping an iron lipped chute over the edge of the skip.

**Quincy Mining Method.[4]**—At the Quincy mine narrow amygdaloid lodes, dipping at an angle of from 54 degrees to 38 degrees, are being worked at great depth. The conditions are somewhat similar to those at the Calumet and Hecla conglomerate mine, but comparatively little timber is used. Support is chiefly by rock pillars, and by heavy stulls loaded with broken rock. Drifts, 7 by 6 feet, are run in the lode. Commonly the drifts are partly in the foot-wall. The miners driving the drift are closely followed by others cutting out the lode for a width of 18 feet from the foot-rail. Following the miners making the cutting out stope come timbermen who protect the level and make provision for drawing off the ore into tramcars. When a cutting-out stope has been timbered and the levels ready, drills are started in the stope. The several groups of men are all gradually working their way from the shaft to the boundary.

The level timbering was formerly of stulls placed about 4 feet apart and covered with cedar poles. The present method differs in the absence of lagging consequent on close spacing of the stull timbers. This gives better protection from falling rock and is said to be cheaper. The stull are logs of peeled hemlock, maple and birch, averaging 15 inches to 24 inches in diameter—some are 3 feet in diameter. These are set in a row at the foot of the stope, and are only four or five inches apart. At intervals of 15 feet a 5-foot space is left and a high sollar is built. A 2-foot hole is left so that the ore can be run out onto the sollar. In some parts of the mine the ore is run out on timbers over the level and dropped into the car.

In stoping there are numerous pillars left scattered irregularly in the stope wherever the lode is poor or where support is especially required. Many are in places where the hanging bellies down. In places stulls are set in the stope for support, either as single sticks or in batteries of three. In some stopes the workmen stand on rock-covered platforms supported by stulls and work down the stope from either side of a raise.

A common practice is to have three drills working on the face towards the boundary. Each takes off a slice by five or six breast cuts in descending order, and then goes up in the stope and works down again, taking off another similar slice.

When the stope is mined out, the row of heavy stulls at the foot is heavily loaded with rock. This "poor rock" is commonly obtained by breaking into the footwall, as it is desirable to disturb the hanging as little as possible. Rock is piled onto the stulls to a depth of 30 or 40 feet. Later, as the hanging settles down, the stulls are compressed—often splitting longitudinally, and shortening 6 or 8 inches—and then the rock filling wedged tightly into place, takes up the pressure.

The ore is drawn off onto the high sollars and loaded into tramcars. For short distances, 500 to 600 feet, the cars are pushed by men. After the distance becomes greater, electric locomotives are used to haul trains of 4 or 5 cars loaded with about 3 tons each.

The ore is not loaded from tramcars into skips, but is emptied into ore pockets near the shaft. From these pockets, some of which hold 100 skiploads, the ore is drawn off[5] at a lower level into the skip.

**The Baltic Mining Method.**—The Baltic is one of several mines on the Baltic lode, which is wide, 15 feet to 60 feet, and has an unusually steep dip—73 degrees.

Shafts are sunk in or near the foot-wall, and levels are about 100 feet apart. Drifts are either run 8 feet by 8 feet and then cut out the full width of the lode, or else run the full width at once. Then another cut is taken off the back, the drills being mounted on broken ore. There is then an opening 16 feet high for the width of the lode. The ore is drawn off, and the broken waste rock left in piles in the drift. The levels are now enclosed by "dry" walls built of rock, and a cover of lagging laid on heavy timber caps. Openings are left at intervals in the wall for chutes to draw off ore through mill holes. The mills are built up with a circular wall of rock, leaving an opening about 4 feet in diameter. Iron lips are placed at the chute, so that the ore can be drawn off from the flat bottomed mill holes into tramcars.

When walls are built and mill holes started, the remaining space is filled with poor rock. Then stoping is started, the drills being rigged up on the waste. Where the amount of poor rock broken is too small for the filling required, additional rock is broken from the foot or hanging in "poor rock stopes." The ore broken is sorted where it falls. The waste is left to fill in the stope, and the ore is thrown into, or carried in small cars to the mill holes. Stoping proceeds in this way, the mill holes being built up and the stope filled with waste while the ore is being drawn off.

When the stope has been carried up to within 30 feet of the next level, a so-called caving method is used to remove the arch. A raise is carried up to the level, and numerous holes drilled in the ground on either side of the raise. When the level is no longer needed, a wide opening is made by firing all these holes, and the waste rock filling in the stope aove follows the ore down into the stope below. The ore is sorted out and trown into the mill holes and then drills are rigged upon the waste filling in the stope, and slices are taken off the arch. When only a few feet remain a large number of holes are drilled nearly through to the level, the stope is well cleaned of ore, and then the holes fired. The broken ore falls down into the stope, and is followed by a pile of waste from the stope above. As much of the ore as possible is sorted out and thrown in the mill holes. When all readily reached is sorted out, the drills are rigged up on the side of the pile of waste and another cut is made across the lode. Then again the stope is well cleaned of ore, and the last few feet of back is drilled with numerous holes. These are fired, and another cave of waste takes place. In this way all the lode is broken and most of the ore is saved.

# WATER POWERS IN THE PORCUPINE AREA*

By W. R. Rogers.

For the last report of the Bureau of Mines the writer prepared a few notes on the subject of water powers in the vicinity of Porcupine. This article was incorporated in Mr. Burrows' report on the Porcupine Gold Area.

Since last writing the hydro-electric plant at Sandy Falls has been completed, and electric energy supplied to the mines since June, 1911. Another water power is being harnessed at Wawaitin Falls. Both of these powers, situated on the Mattagami river at distances of 6 and 11½ miles respectively from the Hollinger mine, are shown on the geological map of the Porcupine area.

Other water powers within a radius of 25 miles from Porcupine are: High Falls on the Frederickhouse river in the Township of Mann; Grassy Falls on the Price-Fripp township boundary; and Sturgeon Falls on the Mattagami river in the Township of Mahaffy. Applications have been made for permission to develop all of these. However, no actual development work has been carried beyond the stage of preliminary surveys.

*From the 21st Annual Report of the Ontario Bureau of Mines.

A copy of the regulations stating the conditions upon which water powers are leased may be had on application to the Department of Lands, Forests and Mines.

### Importance of Accurate Data.

Hydrographic work in Canada, or rather the branch of it pertaining to stream measurements, was initiated by the Department of the Interior, Ottawa in 1909. Work, however, has been confined almost exclusively to Dominion lands in the Province of Alberta. A valuable report was issued in 1911 by the Conservation Commission entitled "Water Powers of Canada." In this volume emphasis is laid on the necessity of obtaining more accurate data in regard to water powers before proceeding with their development. The only safe basis for estimating the maximum amount of power available is the minimum flow of the stream throughout the year. In some cases storage facilities will help to raise this minimum. In order to secure the necessary data, metering and gauging stations should be established, and to ascertain the maximum, minimum and mean discharges accurate records for a period of years are necessary. The importance of winter observations must not be overlooked as the minimum flow occurs during that season and should be determined for use in considering power schemes. From the power user's point of view contracts should not be entered into for the supply of more power than is justified by low water records for a period of ten years or more. As such data respecting water powers in Northern Ontario is not available, a very conservative estimate should be made the basis of hydraulic and electrical installations.

A case in point is that of the Porcupine Power Company. Extreme low water and ice troubles in March, 1912, combined to tie up the Sandy Falls power plant and to greatly inconvenience customers. A year previous, at the Ragged Chutes compressed air plant on the Montreal river, a similar condition developed, which resulted in many of the mines at Cobalt shutting down for lack of air to run the drills. This difficulty has been overcome by the construction of storage dams to retain flood waters, in order to increase the flow at low stage periods.

The drainage area of the Mattagami river at Wawaitin Falls is approximately 1,000 square miles. At Sandy Falls the drainage area has been increased to 2,500 square miles by the additional territory supplying tributary feeders, namely, Mountjoy creek and the Grassy and Lost rivers. Assuming a run-off of 0.4 cubic feet per second per square mile, the discharge at these points would be 400 and 1,000 cubic feet per second, respectively. The effective head at Wawaitin is 118 feet, and at Sandy Falls 34 feet. Figuring on this basis and assuming for turbines 80 per cent. efficiency under natural flow, the minimum 24-hour horse-power is 4,300 and 3,100 respectively. The only definite metering records available give the following:—

Wawaitin Falls.—March 1910, 366 cubic feet per second.

Sandy Falls.—January 20th, 1910, 1,654 cubic feet per second.

A director of the Porcupine Power Company states that the extreme low water flow per second at Sandy Falls was 1,600, 1,200 and 600 cubic feet respectively for the years 1910, 1911 and 1912. It will be seen from the above records that an exceptional year like 1912 emphasizes the necessity of continuous records for a period of years to ascertain the extremes of flow as well as a reliable mean. Extreme cold weather, with no thaws of consequence throughout the winter, produces an acute situation in Northern Ontario. Controlled storage is the only remedy for increasing the minimum flow, and it is proposed to dam the headwaters of the Grassy river for this purpose. In this part of the Province of Ontario February and March is the season of extreme low water.

In the case of the Wawaitin plant, Kenogamissee lake forms a small storage basin. Kenogamissee Falls, 25 miles south, affords facilities for storage and regulation. In addition it would be possible to divert the Lost or Redsucker river by means of a small dam and a shallow cutting about 1½ miles in length through sandy soil.

### Porcupine Power Company.

The Porcupine Power Company's plant at Sandy Falls consists of two 25-cycle, 3-phase, 12,000-volt 214 revolutions per minute, 950-k.w. generators, directly connected to S. Morgan Smith turbines. A third unit of similar capacity is being installed. The electric equipment is of Canadian Westinghouse manufacture. Each unite requires 450 cubic feet of water per second to develop full power under an effective head of 34 feet.

Turbine runners are 54 inches, and intake pipe 10 feet in diameter. The turbines were specially constructed to admit of sections being teamed on sleighs a distance of 45 miles from Kelso before the Porcupine branch of the T. & N. O. railway was built. The power house is a timber structure sheeted with galvanized iron, and is equipped with a 15-ton travelling crane. The timber flume, 13 by 16 feet in section, and 700 feet long, is provided with electric heating wires running through the upright studs in case it should be found necessary to use a heating appliance to prevent ice formation in extreme winter weather.

The dam is of cribwork construction, stone filled, sheet piled, and has 10 sluice-ways, varying in width from 12 to 16 feet. Spillway, fishway, and a combination ice run and log chute are also provided.

The plant was designed and constructed by H. D. Symmes of Niagara Falls, who is a director of the Porcupine Power Company.

### Wawaitin Power Company.

Construction work at Wawaitin Falls started in the summer of 1911. Supplies, machinery, etc., were loaded on scows and pointers and towed up the Mattagami river by gasoline boats from Mattagami Landing. Messrs. Ross and Holgate, of Montreal, are consulting engineers for the company.

The Falls are in Thornloe township, their position being shown on the map of the Porcupine Gold Area. It is proposed to use a head of 118 feet, carrying the water from a higher level to a lower by means of an open flume and pipe lines. The open flume or canal is about 1,400 feet long, 40 feet in width, and the greater part is in rock. A 12-foot diameter penstock leads from the flume for a distance of 1,500 feet, where it subdivides into two, each 8 feet in diameter and 1,200 feet long. The surge tank at the junction of the penstock is 40 feet in diameter and 38 feet high. These 8-foot penstocks terminating at the power house supply two units, each Westinghouse generator being 2,500-k.w., 12,000-volts, 3-phase, 25-cycle, running 375 revolutions per minute, with an overload capacity of 3,120 k.w. Provision has been made for a duplication of the pipe line and power house installations. The power house is of reinforced cement construction, with cement roof.

The location of the dam is at the head of a small island, at the point where Kenogamissee lake contracts to river width. This dam, 1,000 feet long is provided with log chute 150-foot spillway, and has 16 stop-log sluiceways for the purpose of maintaining a uniform head above the dam.

E. A. Wallberg has leased this water power, and under the conditions must develop electrical energy to the amount of 4,000 horse-power by September, 1912. During the past winter, 1911-1912, progress has been checked for financial reasons. However, at the time of writing, May, 1912, work has been resumed and indications point to completion of the work before the time required by the lease from the Crown. An interest in the power company has been acquired by the Dome Mines, Limited. They will require 3,000 horse-power for the first year's work.

The Sandy Falls plant of the Porcupine Power Company is already taxed to the limit of its capacity, and further power must be provided to meet the demands of Porcupine mines as development proceeds.

Thanks are due Mr. Robert Laird, resident engineer of the Wawaitin Power Company, for furnishing construction data. Mr. J. H. Thornley, resident engineer of the Porcupine Power Company, kindly supplied photographs of the power house and general layout, and also explained the main features of construction.

# EAST KOOTENAY

Now that the St. Eugene mine is no longer a large producer of lead ore, much interest is taken in the Sullivan mine, to which brief references were made in several annual reports of the Consolidated Mining & Smelting Company of Canada, Limited, as follows:

### Sullivan Mine.

As at June 30, 1910: "A lease has been taken upon the Sullivan mine, near Kimberley. A royalty is paid upon all ore shipped, and the Consolidated company has undertaken to perform $10,000 worth of development work. The mine is producing monthly 2,500 tons of ore containing, approximately, lead 18 per cent., and silver 6 ounces a ton."

As at June 30, 1911: "During the year the company has acquired a majority of the stock of the Fort Steele Mining & Smelting Company, Limited, owner of the Sullivan mine. The lease to the Consolidated company expired on June 30, and the Fort Steele company is now operating the property and shipping ore to Trail. The mine is producing between 2,000 and 3,000 tons a month of ore containing, approximately, lead 20 per cent., and silver 6.6 ounces to the ton. The loss of the St. Eugene tonnage has been serious, but will be partly overcome by the operation of the Sullivan, in which the mineral-bearing area has not yet been thoroughly prospected."

As at June 30, 1912: "The properties of the Consolidated company surrounding the Sullivan group have been prospected to a small extent with a diamond drill, with promising results. The Sullivan lease having expired, the property has been operated by the Fort Steele Mining & Smelting Company, and the ore shipped to Trail for treatment. The mine shipped during the year 21,189 tons of ore, containing 205,654 ounces silver, and 10,569,211 pounds of lead."

Statistics published by the Consolidated company show that up to June 30, last, the aggregate production of the Sullivan mine had been 147,364 tons of ore, containing 1,246,023 ounces of silver, and 63,049,962 pounds of lead, together having a gross value of $3,083,655.

### Economic Geology of Kimberley Areas.

The last-published "Summary Report" of the Geological Survey of Canada includes a report by Mr. S. J. Schofield on his 1911 season's work in East Kootenay. Under the sub-head "Economic Geology" he gives the following information relative to the Sullivan and neighbouring Stemwinder mines, in the Kimberley area:

"The area is situated near Kimberley, the terminus of the Canadian Pacific Railway Company's branch line from Cranbrook to Kimberley, and includes the Sullivan, Stemwinder, North Star, and several minor properties. It is underlain by a series of argillaceous quartzites and pure heavy-bedded quartzites, which are identical in lithological and physical characters with those described in the Moyie district, and hence belong to the lowest-known subdivision of the Purcell series. About one-half mile above Kimber, on Mark creek, a few diorite sills are exposed in the valley walls.

"Sullivan Group.—This group was discovered in 1895; it is situated on Sullivan hill, about two and one-half miles by road north of Kimberley, at an elevation of about 4,600 feet above sea-level. The deposit lies in the lowest-known subdivision of the Purcell series, which here strike about north and dip from 10 to 60 degrees to the east. The country rocks consist of thin-bedded, argillaceous quartzites, and heavy-bedded, purer quartzites. The ore-body conforms in dip and strike with the quartzites and cannot be called a true fissure vein, but a replacement deposit in which the sulphides have replaced the fine-grained quartzites. The hanging and footwalls are, in general, not well defined, but the ore gradually passes into the normal country rocks so that the distinction between country rock and ore is commercial rather than structural. Exceptions to this occur where the walls consist of the thin-bedded, slaty quartzites, which are evidently difficult to replace. In the upper workings, close-folding later than the ore-deposition increases the apparent width of the deposit. On the 60-foot level the dip of the ore-body in places approximates 25 degrees, and on the 100-foot level it increases to 70 degrees, which is also the dip of the surrounding quartzites. As far as exploited, the maximum stope width is 120 feet and the maximum stope length 325 feet. There are nine levels, the deepest being 100 feet below the surface. The deposit is a lens-shaped mass, striking about north and south, with a dip to the east.

"The ore-body is arranged in distinct zones which grade imperceptibly into each other. The centre of the body is occupied by a fine-grained mixture of galena and zinc blende in which masses of purer galena occur as lenses. The gangue is absent from this inner zone, except for a few well-formed crystals of pink garnets. This inner portion gradually passes exteriorly into a fine-grained mixture of pyrite, pyrrhotite, and zinc blende which contains as a gangue numerous crystals of a clear, colorless garnet with some grains of anthophyllite and possibly diopside. The sulphides gradually diminish in amount and finally give way to a fine-grained chert which is present where the country rock is a heavy-bedded, purer quartzite, and is absent where a more argillaceous, slaty member constitutes the wall-rock. No garnets nor anthophyllite are present in this zone. The chert gradually passes into the normal quartzite. The contact minerals occur only in the ore-body and are entirely lacking in the country rock surrounding the deposit. The presenee of the minerals, garnet and diopside, so characteristie of contaet deposits, is not due to any intrusion of igneous material at present visible, for the nearest outcrop of granite is four miles away, near Wycliffe, on the St. Mary prairie. The presence of the minerals garnet,, pyroxene, and pyrrhotite warrants the conclusion that the Sullivan ore-body was formed under eonditions of high temperature and pressure, and in origin was eonneeted with some deep-seated intrusion of granite which has not yet been exposed by erosion in the neighbourhood of the Sullivan mine. The Stemwinder property, oecurring on Mark creek and apparently in a lower horizon than the Sullivan, indicates that ore-bodies might be expected below the Sullivan deposit.

"The Sullivan ore is shipped to Trail for treatment and is smelted without any preliminary concentration. Development and eonstruetion work are being rapidly earried on, and about 100 men are employed.

"Stemwinder.—The Stemwinder is situated one mile northwest of Kimberley, on Mark creek. The country rocks consist of argillaceous quartzites intruded by several sills of diorite. The ore-body is enclosed entirely by the quartzites and closely resembles the Sullivan deposit in its occurrence and mineralogy. The interior of the ore-body consists of a fine-grained mixture of galena and zinc blende passing exteriorly into a fine-grained mixture of pyrrhotite, pyrite, and zinc blende. This is sneeeeded by a cherty layer which in turn passes into normal quartzite. The amount of development so far accomplished was not sufficient to expose the relation of the ore-body, but it is evidently of large size. Three short tunnels and a shaft 75 feet deep open the deposit. Experiments are in progress to determine the best method for the treatment of this refractory ore."

# PERSONAL AND GENERAL

Mr. R. C. Sweezy has been retained by banking interests to examine mining properties. He has returned recently after spending three months in Western Canada, and leaves shortly for Mexico.

Mr. R. H. Stewart, general manager of the Consolidated Mining & Smelting Company of Canada, passed throught Montreal recently, having spent some weeks in England on business for his company. Mr. Stewart is very hopeful concerning the future of mining in British Columbia, believing that great aetivity will result directly the problem of treating the complex ores, particularly those in which zinc is a major constituent, shall have been satisfactorily solved. He is of the opinion the solution of these problems will be found very shortly.

Mr. Charles Fergie was in New York on business last week.

Dr. A. E. Barlow delivered a lecture on the Cobalt District before the New York Section of the American Institute of Mining Engineers on December 20th.

Mr. Moses Jones, assistant underground manager at the Springhill mines, Nova Scotia, was killed on December 19th by being struck by a train of cars passing up the slope.

Mr. J. H. Plummer, president of the Dominion Steel Coporation, who was interviewed in Montreal the other day, stated that conditions now obtaining in the steel trade are very satisfactory. The company has now its fifth blast furnace in operation, while the output of the nail mill has been considerably increased.

Mr. David H. Browne, metallurgist of the Canadian Copper Company, was in New York recently in connection with the arrangements now being made by the company to double the capacity of its reduction works in the early future.

Mr. Herbert Carmichael, of Victoria, B.C., for about twenty years provincial Assayer for British Columbia, has resigned that Office and will hereafter give his attention wholly to his own affairs.

Dr. De Lorme D. Cairnes, of the Geological Survey of Canada, has contributed to the "Bulletin of the Geological Society of America" a paper entitled "Differential Erosion and Eqiplanation in Portions of Yukon and Alaska."

Prof. W. A. Carlyle, professor in metallurgy at the Imperial College of Science and Technology, London, England, recently returned to that city from Mazapil, Mexico.

Preliminary announcement has been made of the intention to hold the next Annual Meeting of the Canadian Mining Institute in Ottawa, Ontario.

Mr. C. D. Emmons, under whose advice the British Columbia Oilfield, Ltd., of Vancouver has been drilling for oil on Graham island of the Queen Charlotte group, British Columbia, is convalescent after having been ill two weeks in a hospital in Victoria.

Mr. Geo. Watkin Evans, of Seattle, Washington, who had been ill after having spent the greater part of the last field season in the Groundhog eoal field, in the northern part of Skeena district, British Columbia, has now recovered his usual good health.

Mr. Henry Harris, some years ago assistant superintendent of the smelting works of the Hall Mining & Smelting Company,at Nelson, B.C., and afterwards filling a similar position at the Brown Alaska Company's smeltery at Hadley, Prince of Wales island, southeast Alaska, sends greetings to his friends in Canada from Zeehan, Tasmania, where for several years he has been manager of the Tasmanian Smelting Company.

Mr. W. Pellew-Harvey, for years activity eonneeetd with the mining industry of British Columbia, but now of Pellew-Harvey & Company, mining engineers, London, England, was recently at Tiflis, Caucasus.

Mr. W. S. Hawley of Spokane, Washington, manager of the Silver Hoard Mines Company, operating a silver mine in Ainsworth camp, British Columbia, has received from Prof. F. A. Thomson, head of the mining engineering department of the State College of Washington, Pullman, Washington, a report on that property, which during recent months has shipped to the Consolidated Company's smeltery at Trail, B.C., between 200 and 300 tons of ore averaging about 61 ounces silver to the ton and 3 per cent. lead.

Mr. Robert R. Hedley, of Vancouver, B.C., was one of the examiners at a recent examination of applicants for certificates of competency and license to practise assaying in British Columbia under the "Bureau of Mines Amendment Act of 1899."

Mr. Jules Labarthe, formely superintendent for a number of years of the Consolidated Mining & Smelting Company's smeltery at Trail, West Kootenay, British Columbia, and now general manager of the Mason

Valley Mines Company, with mines and smelting works in Nevada, when met in Spokane, Washington, recently, stated that Mr. A. J. McNab, who succeeded him in charge of the Trail works and afterward accepted the position of metallurgist for the Mason Valley Mines Company is doing excellent work in Nevada, where his company's mining and smelting enterprise is in a flourishing condition.

Mr. Douglas C. Livingston, one of the professors of mining engineering at the Idaho University, Moscow, Idaho, formerly with the Tyee Copper Company on Vancouver island, B.C., and later for several years engaged in mining in Mexico, has been taking part in a discussion, printed in "Mining and Scientific Press," of San Francisco, California, of an article on "Ore Reserves and Life Extension," contributed to that journal by Mr. Morton Webber.

Mr. R. Machin, well known in British Columbia mining districts six or seven years ago as the provincial representative of several British manufacturers of mining machinery and supplies, is again resident in Victoria after having been for a time in Western Australia on business matters.

Mr. J. W. D. Moodie, vice-president and general manager of the Britannia Mining & Smelting Company, with mines and concentration works near Howe Sound, British Columbia, has been on a visit to New York city, where are resident some of the larger shareholders in the Britannia company, the operations of which are becoming increasingly important, while its property holdings have been considerably added to of late.

Mr. M. E. Purcell, superintendent of the Consolidated Mining & Smelting Company of Canada's Centre Star group of mines, in Rossland camp, British Columbia, has returned from Spokane, and the Coeur d'Alene district of Idaho, after having attended the American Mining Congress, and visited several of the larger mines and concentrating mills in the Idaho Panhandle.

Mr. Byron Riblet, whose name is well known in British Columbia and adjacent parts in connection with the Riblet system of aerial tramways, has been granted a patent for a landing stage for aeroplanes.

Mr. James Rutherford, representing British investors in land and mining properties in Western Canada, has returned to Victoria, B.C., for the winter after having again spent several weeks in the Peace River country.

From the London "Mining Journal" it is learned that Mr. Ernest H. S. Sampson had recently been appointed assayer and surveyor for the New Canadian Metal Company, Limited, at Riondel, British Columbia. This company, of which Mr. S. S. Fowler is general manager, is working the well-known Bluebell mine, situated across Kootenay lake from Ainsworth, West Kootenay, and has, too, a well-equipped concentrating mill there.

Mr. Robert H. Stewart, of Trial, British Columbia, general manager of the Consolidated Mining & Smelting Company of Canada, Limited, who about two months ago left on a trip to Europe, is understood to have been investigating some of the zinc reduction processes in operation on that continent. Interested persons continue to make much of the allegation that the Consolidated company has purchased the Canadian rights to the French process for reducing zinc-lead ores, but so far as can be ascertained that company is doing little, if anything, towards using that process for the attempted saving of the spelter content of ores in any considerable quantity.

Several months ago the Canadian Collieries (Dunsmuir) Limited' operating the Cumberland and Extension collieries, on Vancouver island, British Columbia, created a new office in connection with their operations at Union bay, namely that of superintendent there of workshops, coal-shipping plant and appliances, coke ovens, etc., and appointed Mr. J. A. Tompkins to fill the position. There is a prospect of the company establishing a coal-briquetting plant at Union bay, and in connection with this prospective enterprise much information is being obtained.

Mr. Bruce White, for years actively connected with mining in West Kootenay district of British Columbia, has returned to that district after having spent several weeks in the provincial coast cities and in Spokane, Washington. His name was lately associated in a district newspaper with the staking of mineral claims in the vicinity of Kootenay lake, on which claims the occurrence of ore containing platinum was alleged. Mr. White himself is authority for the statement that there is still serious doubt as to the correctness of the report that platinum occurs there, as alleged, since an assayer of long experience and excellent standing has been unable to confirm assurances given by another that the ore is platinum-bearing.

Mr. W. E. Zwicky, of Kaslo, B.C., manager of the Rambler-Cariboo Mines, Limited, with a largely developed silver-lead mine in Slocan district of British Columbia, has been quoted by the Nelson "Daily News" as authority for the statement that the operation of the company's new concentration mill has been commenced. This company, after having previously sunk to a depth of 800 feet from the apex of the vein, in 1904, commenced to drive a 4,500-foot cross-cut adit with the object of cutting the vein at about 600 feet deeper. Eventually this was done, and after many delays, caused by fire and other adverse circumstances, production on a comparatively large scale is about to be begun. The vein has been explored on half a dozen levels down to the 1,400, and on each of these stoping can be done, so that there is little probability of the supply of ore running short for the next year or two.

Zinc mining is receiving increasing attention in British Columbia, and in this connection, Mr. J. L. Retallack, of Kalso acting on behalf of Messers. Beer Sondheimer & Company, with works at Bartlesville, Oklahoma U.S.A., has purchased the zinc-concentrate output from the concentrating mills of the Standard, Hewitt, and Van-Roi mines,in Slocan district, and the Monarch, near Field, on the C.P.R. transcontinental line. Other shippers are the Lucky Jim and the Noble Five both in Slocan district, the former in comparatively large and the latter in smaller quantity. In addition, there is a little British Columbia zinc ore concentrate being sent to Kansas and elsewhere in the United States.

## QUEBEC.

Some attention is again being directed to phosphate mining in the province in consequence of the improvement in prices permitting of profitable operation. At one time phosphate commanded $25 per ton, but the discovery of large and easily mined deposits in Florida reduced the price to $5 per ton, killing the local industry. The present price ranges between $11 and $14, and there is a good demand for the product. Phosphate is manufactured into fertilizer at five works in Canada, of which three are established in the Province of Quebec.

# THE SWASTIKA GOLD AREA*

By E. L. Bruce.

The Swastika gold area centres about the Town of Swastika at mileage 164 on the Temiskaming & Northern Ontario Railway. The area examined comprises the southern half of the Township of Teck and the northern half of the Township of Otto. This area was first described by Mr. W. J. Wilson, who made a reconnaissance survey of the Blanche river for the Canadian Geological Survey, and later by Mr. L. L. Bolton, who accompanied Speight's survey party in 1904 and reported on the geology of the country from Round lake to Abitibi for the Ontario Bureau of Mines.

At the time of the gold rush to Larder Lake a number of claims were staked in the Swastika area, and some work was done upon them. The claims now held by the Lucky Cross Mining Company and those of the Swastika Mining Company were located at that time. In the depression which followed operations were continued only on the latter group. The first development was done on the big quartz vein on the west side of Otto lake. A shaft was put down about sixty feet and some drifting done. Surface prospecting on the north side of the lake uncovered No. 1 vein, containing visible gold, and with the discovery of other veins near this one the work on the west side was abandoned. A shaft was sunk and a five-stamp mill was installed on the north side. This mill turned out several small bricks before being dismantled in 1911 to make room for the present plant.

The discovery of gold at Porcupine led to renewed interest being taken in the older area, and the summer of 1911 saw most of the old claims restaked and development work started on many properties.

## Topography and Drainage.

The area lies just south of the height of land between James Bay and the Ottawa river, and while the difference of elevation is seldom more than two hundred feet the country is rather rugged and broken. Rock outcrops are numerous, and the areas of swamp are neither large nor continuous. The hills are arranged in roughly parallel east and west ridges in conformity with the strike of the formations. East of the Blanche river, however, the regularity is not so pronounced, and the hills are more or less isolated.

The Blanche river which flows through this area, turns sharply east about a mile below Kenogami station and runs between two of these ridges until it breaks across the southern one in a series of rapids at Swastika. Just south of these rapids it is joined by Amikougami creek, which forms the outlet of Amikougami lake north of Swastika, and which flows in a fairly straight north and south course. Below the junction of the two streams is a broad valley, in which the river meanders considerably before entering Otto lake. Leaving the lake, the river again forms a series of rapids, below which there is a long stretch of quiet water broken only where it crosses the syenite ridge in concession IV. In concession V. the Blanche receives another tributary from the north, known as Murdock creek. This stream, like Amikougami creek, flows south in a fairly straight course. The lower part is shallow and rapid, but the upper reaches are rather sluggish. The Amikougami is broken by a few rapids but forms a good canoe route to the lakes lying to the north.

*From the 21st Annual Report of the Ontario Bureau of Mines.

## Geology.

The rocks of the area may be classified as follows:—

Recent and Glacial—
Stratified clays, peat, sand and gravel.
Pre-Cambrian—
Post Huronian—Diabase, red feldspar-porphyry, augite, lamprophyre.
Igneous Contact.
Huronian—Conglomerate and greywacke.
Unconformity.
Laurentian—Augite syenite.
Igneous Contact.
Keewatin—Gral feldspar-porphyry basic intrusives, iron formation and epidotic rocks, greenstones and schist.

### Keewatin.

**Greenstone and Greenstone Schist.**—The greater part of the Keewatin rocks are massive greenstones or their schistose derivatives. Where stil massive, the greenstones show an ellipsoidal structure. This characteristic is pronounced in the rocks of the northeast corner of Otto. It is also seen especially well on the hill to the east of mile-post 170, and on the face of the cliff near Kenogami station. Massive greenstones grade into rocks of schistose character. The schistoity become more pronounced near the contact with the later acidic intrusives, and the strike of the schists is usually parallel to the strike of the contact. The layers of schist are not at all regular, but often the rock shows a columnar structure, with twisted blocks whose surfaces are serpentinized and highly polished. Rocks of this type outcrop along the railroad east of Amikougami creek. Between this stream and Murdock creek, railroad cuttings show an anticlinal arrangement of these schists. At the western side they have a strike S. 45 W., dip 70 degrees N.W. The dip gradually becomes less steep, until the schists are almost flat. Then the dip increases towards the S.E., and at a point two miles east of Swastika the strike is S. 64 degrees W., dip 80 degrees S.E.

The greenstones and schist extend in a broad belt across concessions IV., and V., Otto and after crossing the Blanche river at Swastika the northern boundary follows Amikougami creek for some distance, and then swings northeast across the southern part of the Township of Teck.

A chistose greenstone east of Swastika consists entirely of actinolite needles, along with sericite and magnetite. A rather more massive rock at the west end of Pike lake has altered to chlorite, with a considerable quantity of carbonates, and has fine particles of sulphides scattered through it. In neither case is any trace of the original structure or minerals left.

At mileage 162 on the Temiskaming & Northern Ontario Railway there is a cutting through a very dense black basaltic looking rock that carries many small lenses of sulphides. Under the microscope the rock shows grains of quartz and a dark sooty material. The rock suggests a baked bituminous shale.

**Carbonate Rocks**—Carbonates occur at several places in the area. Along the north side of Pike lake a narrow more or less continuous band of a much rusted carbonate rock separates the conglomerate from the grap feldspar-prophyry. This band is so altered and its character so masked by the rusty weathering that it is impossible to determine its original nature. In parts the unweathered portion is light green in colour, probably consisting largely of the chrome-bearing mica, fuchsite. Carbonate rocks also outcrop farther west, in lot 12, concession VI., Otto. They are fractured and the fractures are filled by quartz, producing a network of intersecting veinlets. Other small outcrops of carbonate rocks occur in the eastern part of Teck.

**Serpentine.**—The greenstones are often much serpentised along slip planes and on the surfaces of the layers of schist. An outcrop of massive serpentine of small extent was observed on the Crawford claims, about two miles north of Swastika.

**Iron Formation and Epidotic Rocks.**—Banded iron formation, consisting of alternate bands of magnetite and silica, occurs at several points along the southern edge of the Keewatin belt. A rock that seems to be related to it is exposed in the railway cuts in concession V., Otto. This rock consists of interbanded epidote and silica. Iron formation lies a few chains farther south.

**Keewatin Intrusives.**—A large number of dikes of varying character cut the Keewatin greenstones. Some of these are so much altered that they suggest very early intrusions, and probably belong to the latter part of the Keewatin complex. Others, however, are much fresher, and may be of much later date. These are relatively small in area and have been mapped as Keewatin, since their relationship to later rocks is not known.

Diabase dikes are very numerous in the greenstones. In most cases the rock is very badly altered, and there is little doubt that it belongs to the Keewatin complex. Other dikes are, however, quite fresh in appearance, and some of these may belong to the post-Huronian series but at no place was any intrusion of diabase into conglomerates or greywackes observed. A considerable area of a massive igneous rock outcrops in concession V., lots 1 and 2, of the Township of Eby. It is somewhat altered, but still retains phenocrysts of a bronzy colour. Farther north a thin section shows a rock that has evidently resulted from the metmorphism of an igneous rock of a porphyritic type. Some original minerals are still recognizable, and the original structure is not much affected. Feldspar phenocrysts are present and can still be determined as near albite in composition. A few shreds of green hornblende are left, but most of this mineral, which apparently formed the largest number of phenocrysts, has changed over to chlorite. Sericite is also abundant due to the alteration of the feldspathic constituents.

**Feldspar-Porphyry.**—Intruding the greenstones near Otto lake and again on the eastern side of Murdock creek is a gray feldspar-porphyry, which has been included in the Keewatin series. The feldspar phenocrysts show distinctly on the surface. Under the microscope the rock is distinctly porphyritic. The phenocrysts are blagioclase feldspar, near the albite end, set in a groundmass of quartz, feldspar, and hornblende. Considerable alteration has taken place, producing chlorite, sericite, kaolin, carbonates and epidote. Magnetite and chalcopyrite are present. The phenocrysts make up a large part of the rock, the areas of groundmass being narrow.

A thin section of the rock in the railway cut near the water tank at Swastika shows a rather abnormal facies of this rock. Here the ferro-magnesian minerals are altogether lacking, the whole rock consisting of albite, quartz and alteration products such as carbonates, sericite, chlorite, epidote and magnetite. The ordinary type is a quartz diorite-porphyry. This abnormal type approaches a quartz keratophyre.

**Hornblendite.**—Crossing the eastern boundary of Teck is an outcrop of porphyritic hornblendite. It is roughly elliptical in outline and is entirely surrounded by drift, hiding the contact with the Keewatin rocks around it. Near the centre of the exposure, the hornblende crystals are large, often being an inch in diameter, and the whole rock consists of dark minerals. Towards the margin it becomes finer grained, and more light coloured constituents appear. The rock is made up of phenocrysts of green hornblende and brown biotite, with a little magnetite, apatite and titanite. Inclusions of light pyroxene, of the variety diopside, occur in the hornblende crystals. There is very little alteration, and the hornblende is undoubtedly primary. The little secondary material present is epidote apparently from feldspar. The unaltered character of the rock suggests that it may be much later than the Keewatin series, possibly a basic segregation from one of the acidic intrusives.

**Other Intrusives.**—Many other smaller dikes cut the Keewatin at different places in the area. Basaltic dikes from an inch up to sixty feet in width are to be seen in the railroad cuts east of Swastika. In one of these cuts a dike of andesite-prophyry six feet in width intrudes the serpentinized greenstones. It has a very striking porphyritic structure. The phenocrysts are feldspar and hornblende. The former are well bounded tabular crystals of albite showing zonal structure. The hornblende is of the ordinary green variety, occurring in prismatic crystals much elongated. Cross sections of these have diamond shaped or hexagonal outlines, and some of the crystals show distinct zonal growth, an uncommon feature in hornblende. Fragments of biotite, now light green in colour from alteration, and, in some places, completely altered to chlorite and magnetite, occur. Apatite is also present.

A dike of similar rock but showing more alteration occurs on the Reeves claims north of Pike lake. This dike is cut by a narrow mica-lamprophyre consisting almost entirely of greenish biotite, with a little magnetite.

### Laurentian.

All those rather fresh, acidic rocks of the area, whose relationship to the conglomerate is not known, are included in the Laurentian series. In the northwestern part of the district conglomerates were found overlying acidic igneous rocks, although not directly in contact, and containing pebbles very similar to the underlying formation. In other places no relationship was observed. The character of the feldspar, and the presence of augite in the syenite classed as Laurentian, suggests that it may be one member of a series of differentiation products of a parent magma, of which red feldspar-porphyry and augite-lamprophyre, to be described later, are other facies. In the absence of any observed field relationship, however, it has been mapped as Laurentian.

There are three areas of such rocks in the district. The largest of these forms a prominent ridge lying between concession 4 and 5, Otto, and extending east and west. A boss-like mass intrudes Keewatin rocks north of the railway with its centre in H. R. 737. The third is a small exposure south of Perron lake, in the northwestern part of the area.

The contact of the first of these with the Keewatin can be seen in the western part of the township, forming a broad zone. Towards the centre and east, however, the Laurentian ridge is separated from Keewatin rocks by a wide drift-filled valley. The rock consists largely of feldspar, and is often very coarse in grain, the feldspar reaching a diameter of an inch or more. The coarse grained rock is cut by finer grained stringers of the same character, excepting for the size of the constituents. These withstand weathering rather better and stand out from the surface. The cleavage of the feldspars causes the rock to break down rather easily. In thin section the rock exhibits a tendency towards porphyritic structure. It consists of feldspar, augite, biotite, hornblende, magnetite, zircon, apatite and titanite. Quartz is present in the small areas of groundmass that separate the feldspar phenocrysts, but is not very abundant. Chlorite, epidote and secondary hornblende occur as alteration products. The augite is the oldest of the more important constituents, occurring as well formed crystals (Fig. 3), and sometimes as inclusions in the feldspar. The pyroxene is often fringed with uralite. The most striking characteristic of the rock sections is the structure of the feldspar. It has a peculiar ragged, almost brecciated, appearance, which seems to be due to a crude micro-perthitic intergrowth.

The rock is essentially an augite syenite-porphyry.

The second Laurentian area consists of syenitic rocks of similar character, but the feldspars do not attain so large a size. The rock of the third area is not so coarse in grain as that of either of the others, and shows a more distinctly porphyritic texture.

### Huronian.

Huronian rocks occupy the western part of the township of Teck from the boundary line north to the limits of the map sheet and east as far as Swastika. Northeastward from Swastika the contact with the Keewatin is along the course of the Amikougami creek. It then swings eastward again. The Huronian forms a rather high area, rising gently to the north for a mile and a half from the Blanche river, and then breaking into a series of east and west ridges.

For the most part, the series consists of conglomerate and greywacke. These are fresh and unsqueezed away from the contact, but along the borders of the formation, the rock is a slate standing at a high angle and much rusted and altered. At a short distance from the contact, a conglomerate and greywacke are quite fresh in appearance. It may be possible that the highly titled slates represent a series older than the fresher conglomerate, or the relation of the Huronian to the Keewatin may be that of a fault contact.

The conglomerate is massive and shows no bedding. It varies considerably even in short distances, being crowded with pebbles at one place, while a few feet away pebbles are so rare that only careful search will reveal them. Most of the pebbles are well rounded, evidently water worn, fragments of feldspar-porphyry, similar to the gray feldspar-porphyry already described. Reddish, felsitic pebbles also occur and a few pieces of granite were found. Greenstones are common, and fragments of smooth serpentinized rock like that east of Swastika also occur. The most striking constituents of the conglomerate, although less in number than the others, are the pebbles or jasper varying from the size of a pin-head or less up to a diameter of four or five inches.

Where pebbles fail, the rock passes into a typical massive greywacke. Near the western boundary of Teck, the typical greywacke grades into a reddish coloured rock of an arkose type. Thin sections of a typical variety show fragments, most of which are porphyry, with feldspar or green hornblende phenocrysts. Along with these are fragments of minerals, consisting of albite, quartz, hornblende and magnetite set in a matrix of finer material of the same kind. Secondary minerals, chlorite, sericite, and kaolin are present.

### Post-Huronian Intrusives.

There are at least two igneous intrusives that are later than the sedimentary rocks. These are of distinct types and their relation to each other is not known. Both occur as dikes cutting greywacke and conglomerate, and sometimes as masses of considerable area.

One of these is a light reddish rock with a tendency to develop feldspar phenocrysts. A small knob of this rock is encountered in the first railway cut west of Swastika. It extends but a short distance south of the railway, and sends off a tongue along the base of the hill of conglomerate that rises south of the right-of-way. The conglomerate along the contact is considerably altered and the pebles squeezed and drawn out. East of Amikongami creek is another small exposure of similar rock, and on the Costello claim a small exposure of greywacke is cut by at least three different dikes of this rock. Many other small dikes of the rock occur at different places in the conglomerate.

A specimen from the cut west of the station shows under the microscope a rather granitoid texture, and consists almost entirely of an acidic plagioclase feldspar with a considerable quantity of secondary products. Dolomite is the chief of these, occurring in small rhombohedrons massed together, or in veinlets through the feldspar.

Aggregates of epidote and other secondary minerals are present and a little chalcopyrite is scattered through the section.

The small quantity of orthoclase probably unites with some of the soda to form anorthoclase. Hornblende does not occur in the sections examined, and that shown in the norm represents minerals such as epidote, chlorite, and other secondary products.

**Augite Lamprophyre.**—The other post-Huronian intrusive is basic in character. It is black and weathers with a pitted surface. On a fresh fracture it sometimes shows a faint purple shade. Parts of the rock show aggregates of secondary minerals which give it the appearance of having an amygdaloidal structure. This general character suggests rock of the Keewatin complex, but on a small point on the south shore of Elsie lake, near the west end, a narrow dike of this rock striking northeast cuts the greywacke. Other dikes of the same rock occur at points on the trail north to this lake, and some of these include fragments of Huronian in them.

On the north bank of the Blanche river in the township of Eby, augite lamprophyre forms the face of the high bluff for some distance. The contact is on the top of the ridge and near it the lamprophyre is bracciated and recemented by the same kind of rock.

Thin sections show numerous phenocrysts of augite set in a groundmass made up of needle-like feldspars and smaller augite crystals. Magnetite is scattered throughout in considerable quantity, also apatite, both as inclusions in the phenocrysts and the groundmass. Chlorite and epidote occur as alteration products. The augite is green in colour and occurs in well formed blocky crystals (Fig. 5 and 6). The feldspars are too small to be determined optically. The apparently amygdaloidal portions mentioned before are areas of secondary minerals, but they seem to be replacements of certain parts of the rock rather than fillings of vesicular spaces.

Since the kind of feldspar could not be determined, the relation of augite to anorthite as calculated may not represent the true proportions of the rock.

### Pleistocene and Recent.

The Pleistocene is represented only by unsorted sands and gravels, and these do not exhibit great development in the area. Since Pleistocene time the streams have formed alluvial plains in favourable places along their valleys. The largest of these is along the Blanche river in concession 5, Otto. In the swampy and marshy areas between the rock exposures peat has formed to some depth. South of the area, towards Round lake, the Pleistocene and recent deposits are a much more important formation.

### Economic Geology.

The rocky and broken character of the country makes it quite unsuitable for agriculture, excepting in the limited areas where streams have formed alluvial flats. Farther south, near Round lake, some farms have been taken up.

Fires have destroyed the original forest, but the part north of the Blanche river supports a considerable second growth, mostly of birch and poplar. This is rather light near the river, but becomes denser farther north.

### Gold.

Visible gold occurs in quartz veins in at least two parts of the district. One lies near Otto lake and includes the Swastika mine and the Reeves claim. The other lies east of Amikougami creek, on the Lucky Cross Mining Company's claims.

The veins are of the usual rather lenticular type, as a rule with steep dips. The quartz is of the white crystalline variety, with dark streaks showing in it. A slight fracturing follows the first quartz deposition, and tiny veinlets of a more transparent variety cut across the older quartz, like water lines on paper. Sulphides occur in the veins, as chalcopyrite and pyrite. The gold is very often associated with the sulphides or with the dark lines in the quartz, but occasionally is found in the clear quartz. On the Swastika claims the veins cut greenstone and gray feldspar-porphyry. On the Reeves and neighboring claims the wall rock is feldspar-porphyry and the rusty carbonate rock. The relationship on the Lucky Cross veins is similar to that on the Swastika. The porphyry is in small dikes and sometimes forms one wall, occasionally for a short distance both walls, of the vein, which does not seem to vary with change of country rock.

Veins of very similar physical characteristics are found in the conglomerate and greywacke, but, so far as known, no values have been found in them. It may be possible that they are of different age than the veins found in the Keewatin rock, or, if of the same age, the Keewatin rocks have favoured precipitation of values where veins cut them. If the latter explanation is correct, it seems likely that the fracturing of the rock and deposition of the vein material and gold values is due to the post-Huronian intrusive rocks, and probably more to the acidic type than to the augite-lamprophyre.

### Active Properties.

The Swastika Mining Company has done most of its development work on three veins on the north side of Otto lake. The largest of these is eight to nine feet wide, striking north and south. This is intersected by two other veins, the smaller having eight to nine inches of quartz. Most of the ore already stoped has come from the large vein above the thirty-five-foot level. The mine now has a three-compartment shaft down two hundred feet, the old shaft being used merely for ventilation. Considerable drifting has been done. A new equipment has been installed, consisting of two 125-horse power Jenckes boilers, a 10 by 12 double drum hoist and a 12-drill Sullivan compressor.

On the Reeves claims north of Pike lake, two veins, eight and nine feet wide, have been stripped for a hundred feet or more. These veins strike N.E. and S.W., and are about fifty feet apart. In the larger of the two, visible gold occurs at its junction with the small quartz vein.

On the Lucky Cross claims visible gold was found first in a small vein that shows in the railway cut just east of Amikougami creek. North of the right-of-way this vein is about eight inches wide and carries visible gold in a band crossing the vein at an angle from wall to wall. Later prospecting has uncovered other veins north of this, one of which has a width of twelve feet. A plant including a 6-drill compressor has been installed.

The Homestead Mining Company has a vein in the rusty carbonate rock near the Huronian contact, on which they are driving an adit into the hill.

The observations on the area were made under the general supervision of Mr. A. G. Burrows, who spent a few days with the writer in the field. Mr. R. M. Smith acted as assistant during the season. Valuable advice and assistance in the petrographic determinations were received from Prof. C. P. Perkey, while the data were being worked up in the Department of Geology and Mineralogy at Columbia University.

# SPECIAL CORRESPONDENCE

## ONTARIO.

### COBALT, GOWGANDA AND ELK LAKE

**ORE SHIPMENTS OVER THE T. & N. O. RY. FOR THE MONTH OF NOVEMBER, 1912.**

**Cobalt Proper—**

| Mine. | Tons. |
|---|---|
| Beaver | 64.37 |
| City of Cobalt | 42.00 |
| Cobalt Lake | 151.43 |
| Crown Reserve | 19.61 |
| Coniagas | 215.38 |
| Cobalt Townsite | 87.65 |
| Hudson Bay | 93.26 |
| Kerr Lake | 92.00 |
| La Rose | 260.62 |
| Nipissing | 31.62 |
| McKinley-Darragh | 135.44 |
| O'Brien | 64.79 |
| Penn Canadian | 34.46 |
| Peterson Lake (Seneca Superior) | 191.63 |
| Temiskaming | 66.22 |
| Trethewey | 58.00 |
| | 1,608.48 |

| | |
|---|---|
| **Gowganda—** | |
| Millerett | 10.00 |
| Silver ore shipments, total | 1,618.48 |
| **Iroquois Falls—** | |
| Alexo Mine( nickel) | 300.65 |
| Total | 1,919.13 |

Silver ore was shipped as follows: Canada, 31.86 per cent.; United States, 68.14 per cent.

**Fire Losses.**—Two companies lost their plants by fire during the past two weeks. The Seneca Superior, after shipping five cars of ore, one high grade and four low, had the misfortune to lose the whole of their surface equipment and development, will be delayed a little. The other victim was the Twentieth Century, a little company operating a small plant on some claims between North Cobalt and Cross Lake. Two years ago it is stated a diamond drill core contained high silver values, and they were cross-cutting for the vein when the catastrophe occurred. Both plants will be re-built.

**Mutual Benefits.**—It is probable that La Rose will benefit almost as much by the discovery of another vein of high grade ore on the Right-of-Way, as the Right-of-Way itself since the vein has been drifted on right up to the boundary and here it is three or four inches wide and high grade. The Right-of-Way is drifting to tap it at the 140-foot level, while the La Rose is also cross-cutting for it. They cannot fail to find it and should have an entirely new ore shoot about 100 ft. long on their own property.

**Buffalo Property.**—The Buffalo mine has already made three "pours" from the new high grade mill, and the mill seems to be working efficiently with the least possible delay. The third "Pour" just shipped to England consisted of 64 bars of bullion, containing 60,628 ounces of silver worth at the market $38,500. In the last three months the Buffalo has produced more ore than at any previous time in its history. Everything is now being converted to bullion, both the concentrates from the mill and the high grade, hand-picked from the stopes. The new vein at the 460-foot level of the Beaver mine is improving as more work is done on it. It has now widened to four inches of high grade ore. It is in virgin country and open possibilities for country that has not heretofore been considered favorable for prospecting.

**Lake Rumours.**—It is stated that an English syndicate connected with the same group operating the Cobalt Townsite and the Casey Cobalt has taken options on a large quantity of stock of the Cobalt Lake Mining Company. The options extend over a period of thirteen months and prices vary from 43 cents for the first twenty per cent. to slightly more than par. The Casey Cobalt will resume shipments as soon as the roads between the mine and the railroad are good for sleighing. Considerable shipments from mill and mine should be made before the end of the year.

**Sterling Silver.**—The Sterling Silver Mines, Limited, has just been organized with a capital of $1,500,000. They will take over the Haentchel claims on Hubert lake, near Elk lake, and will commence operations at once. It is stated that $13,000 has been spent on these claims already.

**A Slow Start.**—The big low grade mill at the Nipissing dropped only ten to thirty stamps in November and will not add very materially to the Nipissing total this year. In prospecting at the old Kendall vein another good shoot of high grade ore has been cut and is now being drifted on. Under the open cut at the Little Silver vein an ore shoot one hundred and fifty feet long has been opened up. The vein is very high grade, but only an inch wide. In the intermediate raise at the 64 shaft the vein where it is now being stoped shows twelve inches of high grade ore. As a direct consequence of the new vein on the Seneca Superior lease the Nipissing is sinking its old 86 shaft in order to cross-cut the territory in the vicinity, for this vein. All the silver shipped last month was in the form of bullion.

**Gillies Limit Active.**—There is considerable activity on the claims staked in August in the Gillies Limit, all prospectors believing now that the danger of dispute is past. So far there has been no find of any magnitude. On the Ryan claim some leaf silver has been discovered in a heavy smaltite and niccolite vein, but that is the extent of the bag so far.

**However, They Are Found.**—Two prospectors have set up with a team of dogs for Moose Factory, where they hope to hear tidings of the Donaldson party. Some six or seven members of this party (Cobalt men in charge of a McGill graduate) should have been out some months ago. It is hoped that they are safe at Moose Factory waiting for the ice to become safe on the Mattagami River, but their friends are nervous. They were last seen at Great Whale River on the east shore of Hudson's Bay and they were then making their way south in a sail boat.

## PORCUPINE AND SWASTIKA

**Strike Dragging.**—The strike still trails its weary length. For the most part, under the protection of the Provincial Police, the mine operators have been enabled to get in strike breakers, but in several occasions the strikers have induced them not to go to work. The McIntyre mine thus lost most of a shipment of men. The Hollinger has now almost a full complement of men, but the efficiency of the miner who has taken the place of the striker is not very high. However, both mine and mill are running and will no doubt do so. At the Dome the effects of the strike are vanishing. Under a strong guard of private detectives the pipe line from the Dome mill to Porcupine lake is being laid. Otherwise work is going ahead much as usual and as a matter of fact owing to the running into a patch of high grade ore the bullion shipment for November was higher than for any previous month in the history of the Dome. The Pearl Lake, Three Nations, and Schumacher have made their peace with the union and are working. The Dome Lake has a full force of carpenters at work on the mill and the McEaneny are also proceeding rapidly with the work of construction interrupted by the strike. Nowhere apart from the Dome and the Hollinger is there much attempt to continue underground work, with the exception of the McIntyre, and here, too, the chief desire is to complete the new mill. The Vipond, Jupiter, and Plenaurum have allowed their workings to fill up and have resigned themselves to a winter of idleness and no doubt if a settle is not soon effected, others will follow their example. The strikers are no longer molesting workmen engaged in assessment and in this respect the camp is quite active. It would have been very active, indeed, but for the strike. All the cases brought against the Hollinger workmen under the Lemieux Act, have been put over until January 6. A number of men on both sides have been fined for minor acts of violence and the situation is generally very peaceful. The chief sufferers by the strike are undoubtedly the merchants in the settlements at Timmins, Schumacher, and South Porcupine. They were just beginning to recover after a very slow summer and this setback will be fatal to many of them. Hundreds of the best miners have left the camp.

**Tough.**—Mr. C. A. Foster, who is operating the Tough claims near Kirland lake, Swastika is assembling a carload of high grade gold quartz ore for shipment. It is understood that twenty tons will be sent out at the end of this week or the beginning of next. The shipment will certainly cause considerable interest, and as it will be the richest shipment of gold quartz ore that has ever left the north country for a smelter. The vein still looks very good where the ore has been open cut and work is proceeding, a shaft being sunk in order to cut the vein at depth. There are also other properties that exhibit indications of making good around Kirkland lake. Jim Hughes and Sandy McIntyre, who are working the Reamsbottom claims state that they have opened a fine looking vein eight feet wide. The assays are said to be good.

**Morrisette Township.**—Claims in Morrisette township, east of Kirkland lake, owned by Dr. Dorsey and Dr. Fisher, of New Liskeard, have been optioned to a syndicate who are bound under the agreement to spend a considerable sum of money on them to open them up.

---

It is said that the result of diamond drilling at some of the properties of the Dane Mining Company, between Dane and Swastika, has not been unfavorable, and it is understood that mining operations which were suspended for some time will be resumed for the winter.

---

The Alexo mine at Iroquois Falls continues to output a good tonnage of nickel each month. Last month there was despatched over 300 tons. A small plant will be installed this winter, all the work so far being done from the surface and by hand.

---

## BRITISH COLUMBIA.

With December half gone at the time of writing, and the chief interruption in the mineral production of the year being only the strike of coal miners at the coal mines, on Vancouver island, of the Canadian Collieries (Dunsmuir), Limited, there appears to be good reason for thinking that the estimate of total value of the year's production, as printed in The Canadian Mining Journal of June 15, last (see p. 446) will be found to have been a reasonable one—in fact, it is quite probably final returns, to be received during the first quarter of 1913, will show that it was somewhat under what the actual total value will have been. In detail the estimate will be too high in regard to some of the minerals, but this has been compensated for by a larger production of others than was expected, or possibly a little higher average price. The position appears to be, however, that the total value, then placed at $31,500,000, will have been reached, and probably passed.

### SOUTHEAST KOOTENAY

The following news notes of Southeast Kootenay have been taken from the "District Ledger," Fernie, Crow's Nest Pass:

The C.P.R. are keeping Corbin stocked with cars, and the mines are turning out more coal than ever, which speaks well for the quality of the coal being dug at present.

The employees of Michel collieries have decided to ask the chief inspector of mines to appoint inspection committees for the various mines in Michel.

Norman Henderson, master mechanic at Michel, has resigned his position. He has some good positions offered elsewhere, but as yet has not made up his mind where to go.

Mr. P. L. Naismith and Mr. Lewis Stockett, of the C.P.R. Department of Natural Resources, were in Hosmer from Calgary recently.

Surveyors working under instructions from Mr. Jas. T. Laidlaw, Cranbrook, have been surveying claims in the Flathead district for Mr. John Livingstone, Cranbrook, and a lot of the McLean properties situated in the valley.

The British Columbia Oil and Coal Development Company is still hard at work freighting its boring apparatus into the Flathead country, where its property is situated, up in Sage Creek district.

It is looking promising for a railway being built and a mine or two opened next year. The Southeast Kootenay Railway, which may be better known as the Davis Railway, is going ahead. Mr. Simonds is in charge out at the townsite, where they have built some fine shacks for their camp for the winter. They are going to cut the right-of-way of the railway throughout the winter. Mr. Jas. Macdonell, "Big Jim," has the contract, and his teamster, who has had charge of the freighting for the last three or four months, has got in a full supply of stores, ta last all winter.

### AINSWORTH DIVISION

The Eureka group, situated about a mile and a half north of Sproule, a stopping place on the Kaslo and Slocan Railway, is being worked by the Eagle Lode Mining Company, of Spokane, which company is stated to have spent on the property during the last twelve months about $15,000. Work under the present auspices was commenced about November, of 1911. Six men are employed now, and it is intended to work throughout the winter. The Eureka camp is about 3,000 ft. above the railway, and 6,100 ft. above sea-level.

After driving a cross-cut tunnel 340 ft. to the vein, and then drifting 100 ft. on the vein, the company put in track and prepared to work the lower tunnel of the old workings, from which a drift had been driven 200 ft. Work has had to be suspended in these old workings for the winter, but will be resumed next spring. Meanwhile development is being continued in the new workings. It is intended to next year make such arrangements as will permit of work being carried on in both old and new parts of the mine—in winter as well as in summer. There is reported to be here a well-defined vein of high grade silver-lead ore, two to eight ft. in width traced for 4,500 ft.

### SIMILKAMEEN

The Hedley Gazette has lately been reprinting a description of "B. C.'s Banner Gold Mine"—the Nickel Plate group, near Hedley. Concerning haulage of ore, it says: "The ore is loaded into two-ton cars in the mine and hauled from the stopes about two miles on an electric railway, 3-ft. gauge, in trains of about 25 tons each; maximum grade, 5 per cent. The electric locomotive weighs 10 tons. The ore is then dumped by automatic dumper into the ore-bin at the head of the gravity tramway, which is a three-rail tramway, about 10,000 feet long, and the difference in elevation between the upper and lower terminals is about 4,000 ft. The loaded skip of seven tons going down draws the empty skip up. The tramway is operated in two sections by two men who handle about 200 tons in eight hours. This is probably one of the longest three-rail gravity tramways in the world. It is operated continuously throughout the winter."

# STATISTICS AND RETURNS

## COBALT ORE SHIPMENTS

The shipments from the Cobalt camp for the week ending December 27 were:

| | High. | Low. | Tons. |
|---|---|---|---|
| Townsite | 2 | .. | 121.17 |
| La Rose | 1 | 2 | 121.17 |
| Cobalt Lake | 1 | .. | 30.10 |
| Nipissing | .. | 1 | 43.97 |
| Crown Reserve | 1 | .. | 19.94 |
| Trethewey | 1 | .. | 27.01 |
| Buffalo | 2 | .. | 59.71 |
| Colonial | 1 | .. | 23.33 |
| Wattlaufer | 2 | 1 | 50.00 |
| Peterson Lake (Seneca-Superior lease) | .. | 1 | 41.18 |
| Drummond | 1 | .. | 30.08 |
| Bailey | 1 | .. | 20.00 |
| Total | 13 | 5 | 534.24 |

Bullion shipments:

| | Ounces. | Value. |
|---|---|---|
| Nipissing | 58,464.00 | 36,756.00 |
| O'Brien | 15,736.00 | 9,722.00 |
| Buffalo | 10,550.00 | 6,600.00 |
| Miller Lake, O'Brien | 946.00 | 788.00 |
| | 85,696.00 | $53,866.00 |

## B. C. ORE SHIPMENTS

Ore production for the week ending December 21st totalled 53,064 tons, an increase of about 1,000 tons over the previous week, making the output for the year to date 2,478,767 tons. Smelter receipts for the week were 45,749 tons, and for the year to date 2,202,872 tons.

The Rio mine in the Slocan, which is being operated by a Spokane company, under the management of W. E. Zwicky, of the Rambler-Cariboo, made its second shipment of the year, sending 12 tons to the smelter. With a shipment of 97 tons the Rambler-Cariboo appeared on the list after having been absent for several weeks.

Among the Sheep Creek district silver-lead mines the Emerald and the Hudson Bay resumed shipments, the former sending 104 tons to the smelter. Roads throughout the district are now said to be in excellent condition for sleighing and ore shipments are consequently expected to increase materially in the next few weeks. Rawhiding is commencing. Ore production in detail:

| | Week. | Year. |
|---|---|---|
| **Boundary.** | | |
| Nickel Plate, milled | 1,500 | 74,600 |
| Jewel, milled | 200 | 3,800 |
| Snowstorm | 219 | 883 |
| Ben Hur | 381 | 883 |
| Jewel | 31 | 31 |
| Knob Hill | 26 | 2,148 |
| Granby | 24,040 | 1,232,650 |
| Mother Lode | 7,268 | 362,491 |
| Unnamed | 28 | 11,041 |
| Rawhide | 6,075 | 250,379 |
| Napoleon | 599 | 13,705 |
| Other mines | .... | 29,301 |
| Total | 40,367 | 1,981,898 |
| **Nelson.** | | |

THE No.3--X
MILBURN LIGHT

# Read What This Mine Supt. Thinks of the Milburn Light

The Milburn Light has proved a most effective light for tunnels, sewers and mines. The flame is not affected by currents of air, requires little oxygen for its consumption, does not vitiate the atmosphere like oil or gasoline lights, is smokeless and incandescent, can be regulated from the maximum light to a needle point, lights instantly and requires no attention during use, burns more than half air, and is extremely economical. Over 70,000 lights in use.

*The No. 3-x Milburn light shown here will furnish from 5,000 to 12,000 candle power at a cost of from 4 to 6 cents per hour. Lights 1,500 feet.*

**The Canadian Copper Company.**

Copper Cliff, Ont., Jan. 17, 1910.

The Alexander Milburn Co.,
Baltimore, Md.

Gentlemen:

Replying to your letter, inquiring as to our experience with Acetylene Lights for lighting in the mines, we would say that, after our first trial of Acetylene Lights underground five years ago, we found them so much superior in every way to any other light formerly used that we immediately procured lamps for all our stopes, both underground and in open pits.

We have used Electric Search Lights, Arc Lamps, and Gasoline Blast Lamps. The Searchlight localized the light too much. The Arc Light cannot be used in low back stopes, and cannot readily be moved out of danger from blasting. The gasoline torch gives off soot, and the light is not so white as that from an Acetylene Lamp, and with us this is important, as it is sometimes necessary to sort the Nickel and Copper ore, the two metals being indistinguishable except in a white light.

The Acetylene Lamp is extremely portable, and can be placed in the stopes in front of the men, and changed from time to time, as becomes necessary, without causing delay. No reflector is used and the light is evenly diffused.

We consider Acetylene an ideal light for underground stopes, and for this purpose we use them exclusively. We are said to have the best lighted stopes in the world.

The Milburn Lamp requires less attention, and gives more light than any we have yet tried. They are also perfectly safe.

While we have no accurate figures of cost, we are satisfied that the superiority of the lighting enables the men to accomplish an amount of work so much in excess of the difference of cost between this and any other lighting we know of, that we would use them if they cost twice as much as they do.

Yours truly,
John Lawson,
General Superintendent.

# PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assaye. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

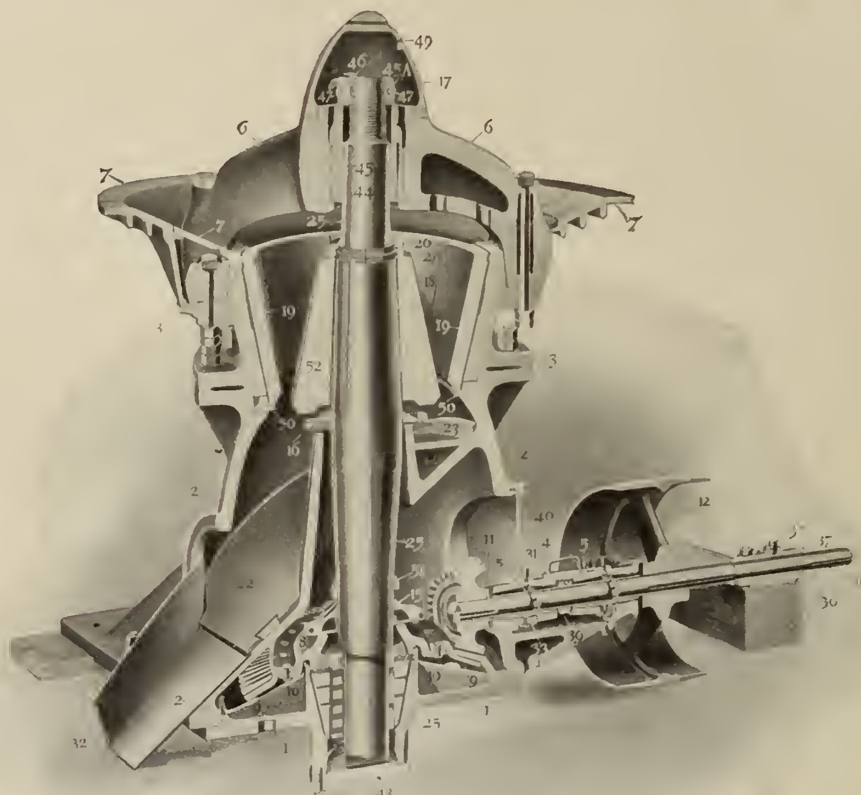
# GATES "K" BREAKER



SECTIONAL VIEW OF GATES "K" BREAKER

## WHY GATES " K " BREAKER IS BEST

REQUIRES LEAST POWER TO OPERATE :— This machine will break more rock per horse power than any other ever made.

EASE OF FEEDING :—The style of spider gives large and unobstructed feed openings which do away with clogging and consequent loss of time in working.

UNOBSTRUCTED DISCHARGE :—No limit of capacity at this point.

HIGHEST RANGE OF ADJUSTMENT :—Provides ease in changing the sizes of product and great facility for taking up wear of the breaking surfaces.

TOP SUSPENSION OF SHAFT :—Prevents the bottom bearings running hot under the hardest work and makes adjustments easy.

STRENGTH AND RIGIDITY :— Due to the liberal proportioning of the parts.

COOL RUNNING :—Because of extra large bearings.

EASE OF MAINTENANCE :—Every detail has been carefully worked out and every part particularly designed to do its work. Each part is easily accessible.

CONCAVES CAN BE CHANGED WITHOUT DISTURBING THE SPIDER OR HOPPER :—Impossible with any other style of breaker.

## Testing for Metallurgical Processes

**By JAMES A. BARR**

216 pages
Illustrated
Indexed

**$2 POSTPAID**

This book is designed to assist in the selection of the process of treatment for any ore. The author describes the apparatus employed in making laboratory and small-lot tests. It is founded upon experimental work at the Michigan College of Mines, and the methods recommended have been tested in practice. It is brief and practical, equally valuable to the student and the practicing engineer.

# Amatite ROOFING

## Best for Mine Buildings

AMATITE is made so as *not to need painting*. It has a real mineral surface which is better than paint. It consists of mineral particles gripped in a firm, tough matrix of pitch—*the greatest waterproofing material known.*

The mineral matter and the pitch form, in fact, a sort of plastic concrete which is thoroughly weatherproof and needs no painting.

Amatite is worth much more to you than any roofing which requires painting every two years. You could well afford to pay a higher price for it. Nevertheless Amatite actually costs *less* than painted roofings of even less weight and will last longer.

The value of a "no paint" roofing, as contrasted with the various painted kinds, is so obvious that Amatite has attained great popularity.

Sample and illustrated booklet free on request.

## THE ONTARIO REPORT

The twenty-first Annual Report of the Ontario Bureau of Mines, 1911, dated 1912, has just been received. The most final compliment that can be paid to this publication is that it is better than those that have been published before.

The Statistical Review by Mr. Thos. W. Gibson, Deputy Minister of Mines, covers the main facts of mineral production in the Province. It is noteworthy that at present 70 per cent. of all the mineral output falls under the category metalliferous. The total value of the mineral output is placed at $41,976,797. This implies an increase of 87 per cent. during six years. But while both classes of products were almost on a parity five years ago, now the metalliferous products outvalue the non-metalliferous by much more than two to one.

Here we may quote Mr. Gibson's own words: "While "the past year was not one of sensational discoveries "or the opening up of new and important mineral "fields, it was one of steady progress and active pro- "duction. The silver mines of Cobalt touched high- "water mark, the nickel-copper deposits of Sudbury "were but little behind their output of 1910 (the largest "yet), the natural gas fields yielded nearly 50 per cent. "more than last year, the blast furnaces turned out "more pig iron, the brick and tile yards more brick "and tile, the quarries more stone, and the long list of "lesser industries, concerned in the production of other "materials were, in general, more busily engaged. At "least one promising mineral area has been revealed "by the untiring prospector—that at West Shining "Tree Lake . . . For the first time in the Province "[also] mercury was recognized . . . Tungsten "[also] was discovered in the form of scheelite by Mr. "A. G. Burrows."

Ontario has a tremendous lead on all the other Provinces. In 1911 its mineral production was valued at $41,976,797. For 1912, the figure, according to the best authorities, will be about $45,000,000; which is practically 40 per cent. of the whole Dominion's output. It is in accord with the direction of modern progress that Ontario is adding to the staff of its Bureau of Mines. That Bureau has already distinguished servants. Its aim appears to be in the right and proper direction. The only possibly fair criticism is that it needs more mining officials.

The Annual Report includes several reports of utmost interest. Two have appeared in these columns. The list covers pretty well the whole of Ontario. Swastika is written up. The Lake of the Woods, Manitou and Dryden, Cripple Creek, and West Shining Tree are not neglected. The geology of Detroit river area is described. The water powers of the region northeast of Cobalt are dealt with. Mining accidents are thoroughly tabulated and classified by the Inspector, Mr. E. T. Corkill. Statistics are given in revised form by Mr. Gibson. And the whole report appears in commendable externals.

The only change that the appreciative critic can fairly suggest is that the report is half a year late. This may be, probably is, due to the printer. The printing shop is the sump of all blame, and the origin of all delays. Yet we believe that it would be worth an effort to bring this and all similar documents out on time.

## THE WABANA MINES DURING 1912

A prosperous year has been 1912 for he Nova Scotia Steel & Coal Company. The output of iron ore from the company's Wabana, (Bell Island), was 564,000 long tons. Much attention was devoted to the submarine mines, although the land areas were consistently worked. The submarine developments included the construction of storage pockets and of transportation facilities, also the installation of several centrifugal pumps, an electric shovel, and electric hoists. The tonnage was thus so increased the daily output was brought up to 1,100 tons. A new concrete and steel machine shop was erected and equipped, also a dry-house with hot and cold running water, to accommodate 500 men. So successful was the dry-house that a considerable extension was deemed necessary.

The new shipping plant at the pier side of the yard comprises tipple, storage pocket with elevating machinery, conveyor pier, and all modern accessories. The total storage capacity is now 70,000 tons. Thus two conveyors are operated simultaneously, giving a combined loading capacity of more han 5,000 tons per hour.

The Nova Scotia Steel & Coal Company is the highest type of progressive, modern, and efficient Canadian enterprise. It is a credit to Nova Scotia and to the Dominion at large.

## THE HAWTHORNE CASE

Whatever the merits or demerits of the Hawthorne outfit, several facts emerge from the legal proceedings that have already been conducted. It is, for instance, a pitiful sight to view the son of Nathaniel Hawthorne under criminal indictment. It is also pitiful to have read the absurdly inflated correspondence that was issued in the name of the several corporations. It is not for us to assign motives, nor is it for us to allocate blame. It is, however, quite obvious that the expert witnesses called by the prosecution told the truth as they knew it. Therefore it is distressing in the extreme to note that no effort has been made to meet the facts adduced by these witnesses. Every effort was made by the defence to discredit reputable men; not one argument was advanced to controvert the statements of the witnesses.

This, of course, is in accordance with the anomalous legal procedure of United States and Canadian courts. It appears to be quite impossible to try any offender on his own merits. The consoling fact is that the trial judge, in this case, is quite beyond reproach.

Let the outcome of the Hawthorne case be what it may, there will remain little inducement for any inspired promoter to attempt similar flotations in the future.

## EDITORIAL NOTES

The rumour of an enormous merger of all Canadian steel companies with certain United States concerns has been emphatically denied by a representative of the Dominion Steel Corporation.

The United Sates Mint sold during 1812, $38,000,000 of gold bars in he United Sates and Canada. In the two countries the consumption of new gold represented about $35,000,000; about one-third of the world's total.

The output of gold in the United States during 1911 was smaller than it has been for five years. The value was $91,700,000, less by $5,200,000 than the value of 1911's output. Silver, however, crept up to about $38,-000,000, which is the highest figure attained in twenty years.

The proposed erection of a large iron, steel, and steel products plant at Sandwich, Ont., by the United States Steel Corporation is most significant. The Corporation owns 1,500 acres of land on the Canadian side of the Detroit river. This includes about one mile and a half of water frontage.

According to the last Dominion census, the value of capital represented by Canadian industries increased 276.19 per cent. during the period 1890-1910. Salaries and wages of employees showed an increase of 204.17 per cent. during the same period, while the total value of products went up 216.24 per cent.

A practical knowledge of mining is a decided advantage in farming. Dynamite is used extensively by American farmers. Low percentage dynamites are customarily employed. While there are many opportunities for utilizing explosives on the farm, the most important are such as blowing tree-planting holes, tree stump blasting, and ditching. For fruit tree planting, the dynamited hole is incomparably superior to the dug hole, as, in the former, the sub-soil is thoroughly broken up, thus giving ample space for the roots to establish themselves.

# FIELD WORK CARRIED ON BY THE GEOLOGICAL SURVEY DURING 1912

(Written for the Canadian Mining Journal.)

During the summer of 1912, the Geological Survey placed in the field over 40 independent and semi-independent geological parties. Special lines of investigation such as those in connection with the coal resources of Canada and the clay and shale deposits, envolved field work over the whole country. The detailed study of the economic possibilities and the general geological structure of various special areas was continued as in previous years. A number of parties were engaged both in the east and west in exploratory work. A considerable portion of the field work of several officers was devoted to making preparation for the various excursions to be held in connection with the International Geological Congress which meets in Canada in 1913 for the first time and which, it is hoped, will prove of great importance to the country as a whole.

Besides the geological parties, five topographical parties were placed in the field in an endeavour to provide accurate topographical maps so necessary for the proper study of the geology of various districts. The value of such maps for many other purposes has long been appreciated.

As a part of its functions, the Geological Survey also carried on special investigation in connection with natural history and the various branches of anthropology.

During the summer of 1912 the field work was completed in connection with the making of a trans-Cordilleran geological section along the main line of the Canadian Pacific Railway. This important piece of work was commenced in 1911 and has been carried out under the general supervision of Mr. R. A. Daly. It is the third nearly or quite complete section of the Cordillera so far made. The first, along the 40th parallel of latitude, from the Great Plains in Colorado to the summit of the Sierra Nevada in California, was run about forty years ago by a United States Government party under Clarence King. The second, along the 49th parallel, from the Great Plains to the Pacific, was made under the direction of the Canadian Commissioner of the International Boundary Commission (1901-7); by his courtesy, the report will soon be issued in reprint form as Memoir No. 38 of the Geological Survey.

In order to hasten the completion of the study of the section along the line of the Canadian Pacific Railway, a number of field parties were engaged during 1912, on this work. Mr. J. A. Allan, in continuation of his work of the previous year, completed the section from Banff to Golden. Mr. R. A. Daly studied the geology along the railway route in the Selkirk Mountains and the Purcell mountain system. This was in continuation of the work already performed in 1911, and amongst other results obtained, the structure of the Purcells, hitherto unknown in the part north of Windermere, was worked out. Mr. C. W. Drysdale was engaged in the study of that portion of the section between Six Mile Point on Kamloops Lake and Lytton, while Mr. B. Rose made a special examination of an area about the west end of Kamloops Lake. Mr. Charles Camsell and Mr. N. L. Bowen studied the section along the railway line from Lytton to Vancouver.

The study of another geological section of prime importance, namely that along the Yukon-Alaska international boundary from the crossing of Yukon River northward to the Arctic, was also complete in 1912. This work was performed in co-operation with the United States Geological Survey which undertook to map the geology between Porcupine River and the Arctic Ocean, while the remaining portion from Porcupine River southward to Yukon River was undertaken by the Canadian Geological Survey. Mr. D. D. Cairns completed in 1912 the geological mapping of this southern part.

Mr. R. G. McConnell made a special examination of the geological section through the Coast Range from Prince Rupert to Aldermere. He also spent a short time examining some of the gold-bearing quartz deposits that are being developed on Princess Royal Island and spent a longer period of time on Texada Island in connection with the recent mining developments there taking place.

Mr. C. H. Clapp engaged in field work on Vancouver Island, geologically surveying the area represented by the Sooke and Duncan map sheets. Certain bodies of gabbro in this general district carry copper sulphide deposits of prospective importance. The recent study of the field has lead to the important discovery that there are a greater number of these gabbro bodies than hitherto supposed. Mr. Clapp also spent some time on Graham Island gathering information concerning the recent developments of the coal measures of the island. It was found that the coal, while of excellent quality, occurs in much smaller basins that was previously thought.

Mr. G. S. Malloch continued his examination of the Groundhog coal basin. The dimensions of the field are, roughly, 30 miles by 45 miles, but the coal-bearing horizon has been removed by erosion from a considerable portion of this area. Mr. Charles Camsell, besides engaging in the study of the section of the Cordilleras along the main line of the Canadian Pacific Railway, also studied a general section from Midway to Spences Bridge. An examination was made of the gold-copper deposits of Kruger Mountain at the southern end of Okanagan Valley, and of the gold-copper deposits on Independence Mountain in the range between Keremeos and Twenty Mile Creeks, Similkameen district. Mr. Camsell made a brief study of the copper deposits at Copper Mountain, Similkameen district, where the British Columbia Copper Company has been for the last year carrying out important development work. The result of this work has been to prove the existence of large deposits of low grade copper ore, which, if they can be successfully treated, will mean that a new and important copper producing field will soon be opened up. A brief study was also made of the Tertiary coal-bearing rocks of White Lake in Okanagan Valley.

Mr. A. M. Bateman made a preliminary examination of the economic resources of the Bridge River district. In this district, mining work is being carried on in the Cadwallader Creek section, where the gold-bearing veins, though small, are persistent and their gold content is sufficiently high to justify mining of the ore on a commercial basis. Mr Bateman also made an exploratory trip from Lillooet to Chilko Lake. As a result of this trip, the eastern border of the Coast Range batholith, which is in many places an important mineral zone, was outlined and the bordering strata were found to be of lower Cretaceous age instead of Palaeozoic, as previously supposed.

Mr. H. Ries, while continuing his study of the clay and shale deposits of British Columbia, made examinations along the Columbia River Valley from Golden southward and from Revelstoke northward. In both districts, deposits of clay or shale, which can be utilized for common and pressed brick and perhaps for other classes of products, were found. A study was also made of the shales of the Nanaimo series on the east coast of Vancouver Island.

Mr. S. J. Schofield made an examination of the part of East Kootenay lying south of the Crown's Nest branch of the C.P.R. and between Kootenay River and Kootenay Lake. The mineral-boarding belt, containing the St. Eugene, Aurora and Society Girl ore deposits, was outlined southwards to the international boundary.

Mr. D B Dowling visited a number of the principal coal areas both in Eastern and Western Canada in order to obtain the necessary information to enable him to make a review of the coal fields of Canada

Mr. W. W. Leach made a detailed examination of an area about Blairmore, which includes practically all the producing mines of the bituminous coal fields on the Alberta side of Crow's Nest Pass.

Mr. J. D. Mackenzie made an examination of the district lying immediately south of the Blairmore map-area. This area includes most of the foothills between the valleys of south fork of Oldman River and Pincher Creek. In it lies the southward extension of the coal areas of the Blairmore district.

Mr E. S. Moore carried on an exploration in the Pre-Cambrian region lying east of the southern part of Lake Winnipeg, partly in Manitoba and partly in Ontario

Mr. C. R. Stauffer completed his studies in connection with the Devonian strata of the peninsula of Southwestern Ontario. This work is of importance in connection with the general problems of the extensive oil and natural gas districts of Ontario. This field of endeavour was further supplemented by the work of Mr. M. Y. Williams, who devoted some time to the study of the Hamilton formation (Devonian) of Lambton County. He was, however, mainly engaged in stratigraphical and palaeontological studies on the Silurian sections of Manitoulin Island.

Mr. W. A. Johnston continued topographical and geological field work in the neighbourhood of Lake Simcoe. An area of about 1,200 square miles surrounding Lake Simcoe has now been accurately mapped on a scale of one mile to one inch with 20-foot contours.

Mr. W H. Collins continued and almost completed a detailed geological reconnaissance of the Onaping map-area lying to the north of the Sudbury district.

Mr. M. E. Wilson made a geological reconnaissance in northwestern Quebec of a belt of country extending from Lake Kipawa via Grand Lake Victoria to the headwaters of Nottaway River.

Mr. H. C Cooke explored the headwaters of Broadback River between Lake Evans and Lake Mistassini, in northern Quebec

Mr. R. Harvie examined a geological section across Brome County Quebec, from Lake Memphremagog westward to Sweetsburg in order to obtain more knowledge concerning the general relations of the older formations. It was hoped, among other results, to ascertain what connection, if any, existed between the copper deposits of Missisquoi Valley and those of the belt found in Sutton, Brome, Stukely and Ely Townships to the west. The subject is of present importance, owing to a renewal of interest in copper mining throughout the general district.

Mr. J. Keele made an examination of various clay and shale deposits in the Province of Quebec and in part of New Brunswick. The principal part of the season was spent in the region adjacent to the St. Lawrence River between Montreal and the City of Quebec, a field containing one of the largest markets for clay wares in Canada.

Mr. W. A. Bell completed his work on the Joggins section of Nova Scotia. This is one of the standard Carboniferous sections of the Maritime Provinces and the elucidation of the various problems there presented are of direct economic value in connection with the development of various coal areas in the region.

Mr. E. R. Faribault continued the geological mapping of the gold-bearing series of the southern portion of Queens and Lunenburg Counties, Nova Scotia.

Besides the various field parties listed above, engaged in field work of direct economic importance, others took up various problems whose scientific importance and indirect economic value can hardly be over-estimated. In Nova Scotia, Mr. J. E. Hyde engaged in palaeontological work on the Carboniferous strata, paying particular attention to the Sydney field. Mr. W. J. Wright studied various problems in connection with the eruptive rocks of the gold field of southwestern Nova Scotia in an attempt to add to the sum of knowledge relating to the origin of the gold-bearing and tungsten-bearing ores.

In Western Canada, Mr. E. M. Kindle engaged in the study of the Palaeozoic section of northern Manitoba. Mr A. McLean carried on palaeontological work in southern Manitoba. Mr. C. H. Sternberg made collections of vertebrate fossils from the Edmonton formation in the vicinity of Munson, Alberta. Mr. C. D. Walcott engaged in work on the Cambrian system of the Yellowhead Pass.

The field work performed during 1912 by the Topographical Division of the Geological Survey, was as follows:

Mr. K. S. Chipman commenced topographical work in the Windermere district. The map, when completed, will include the Columbia Valley from Dutch Creek to Number Two Creek and the country to the west for a distance of about 25 miles.

Mr. W. E. Lawson engaged in work in Lillooet district The topographical map will include a greater part of Bridge River district and the headwaters of Eldorado Creek.

Mr. D. A. Nichols prepared a detailed topographical map of the iron ranges on Texada Island, and also a map of a portion of the northern end of the island.

Mr. B. R. Mackay completed the mapping of the Blairmore area. This map includes all the towns between Coleman and Burmis on the Crow's Nest branch of the C.P.R. and covers the areas in which the principal coal mines are operating.

In New Brunswick, Mr. A. C. T. Sheppard completed a sheet in the neighbourhood of St. John City. This map includes the City of St. John and the Towns of Rothesay and Lorneville. The map will be published on a scale of about 1 mile to 1 inch, with 20-foot contour intervals.

The various topographical maps, when completed, will indicate all cultural features such as roads, railways and buildings, in black; all lakes, streams, etc.. in blue; while relief will be shown by contour lines in brown. The maps can be used for a variety of purposes and should prove very useful.

# REVIEW OF OPERATIONS AT THE DOME MINE, SOUTH PORCUPINE

Written specially for the Canadian Mining Journal.

During the past year, wonderful progress has been made throughout the whole of the Porcupine camp, and at no place has this been more noticeable than at the Dome mine. Following the fire of July, 1911, considerable time was lost in getting in materials, so that a large portion of the heavy construction work had to be performed in the dead of winter, with the temperature often many degrees below zero.

At the beginning of the year, following the appointment of Mr. W. W. Mein as consulting engineer, several radical changes were made in the crushing stations, and also in the mine development plans, so that the real work of the company may be considered to have started at that time.

### Mine.

The ore body consists of a large mineralized zone, in which occur lenses of ore, but the values are so distributed that the whole deposit may be worked with very little sorting. So far, all the work has been done by open-cut methods, and what sorting is necessary is accomplished by cleaning out the stope and then shooting down the waste rock which is trammed out separately.

During the first part of the year, development work was largely confined to the 45-foot level. This was necessary on account of the lack of power and for the purpose of bringing the mine to the producing stage as rapidly as possible.

Raises were put up at intervals, and at the bottom of the raises, chutes or boxes were built. These chutes were built sufficiently strong to permit of blasting large pieces which sometimes get into them. All the mining is open-cut work, the ore being broken into the raises, which are kept full so that large blocks may be sand-blasted at the surface. The actual breaking of the ore is done by hammer drills and a duty of about 50 tons per man per day of 9 hours is attained.

The broken ore is drawn from the bottom of the raises into 16 cubic feet V-shaped side dumping cars, and the tramming is done by mules.

As soon as possible, the development work on the 100-foot level was completed and raises put up to connect with those on the 45-foot level. On account of the greater lift, fewer raises are necessary.

An interesting feature of this property is the incline from the crusher station to the 100-foot level. This did away with the necessity of hoisting the ore through a vertical shaft and tramming it to the crushers, and while serving to develop the west end of the property, is remarkable for its simplicity and the ease and economy with which the tonnage is handled.

The breaking of ore, tramming, hoisting and crushing is all done on the day shift.

### Crusher Station.

The ore is hauled up the incline in trips of four to six cars, and is dumped direct into a No. 7½ gyratory crusher. The broken rock falls on a conveyor belt and is elevated to a pair of No. 3 gyratory crushers, first passing over a grizzley which takes out any material which will pass through an inch ring. This undersize and broken rock from the No. 3 crushers which will pass through a two-inch ring, falls on a second belt conveyor which carries it to the mill bins. The advantage of this method is that both sets of crushers are on the ground so that the construction work is very simple and the crushers are always on a solid foundation.

### Mill.

The mill was designed and erected by the Merrill Metallurgical Company and has fully borne out the promises made for it. It is a steel and concrete structure, covered with two layers of corrugated iron between which was placed a layer of hair felt to provide an insulating material and permit of economically heating the building.

The ore from the 1,600 ton bins is crushed through 12-mesh by 40 stamps of 1,250 pounds each, the pulp passing over the primary amalgamating plates to four Dorr classifiers. These primary plates are to be discarded as the scouring action of the coarse pulp prevents efficient amalgamation. From the classifiers, the slimes pass over a second set of amalgamating plates and then direct to the Dorr thickeners, the coarse sand going back to the tube mills. The product from the tube mills is pumped back to the classifiers, this process being continuous. From the Dorr thickeners, the pulp is elevated to four Pachuca air agitation tanks 40 feet high by 8 feet in diameter, the cyanide being added at the elevator boot. From these tanks, the pulp passes two Dorr thickeners and then to a mechanical agitator which is used solely to prevent the solids settling before they are sent to the presses. These presses are Merrill pressure filters, and have been found to be most satisfactory for this class of ore. The presses discharge into Dorr thickeners, where some of the water is saved and is used again as wash water.

The precipitation takes place in Merrill zinc dust presses, the resulting product being treated first in a small blast furnace with litharge. The lead bullion is then cupelled, the product being remelted in an oil-heated tilting furnace.

The mill is efficient, and ore extraction of 97 per cent. is attained. Of the total gold recovered, about 60 per cent. is obtained from the amalgamating plates.

The treatment of this ore does not present any metallurgical difficulties, the only troubles being of a mechanical nature. The stamps have a duty of 10 tons per day, but the tube mill and press capacity is only 350 tons per day. A new tube mill and filter press are being installed and, when these are in operation, the mill should treat 400 tons daily.

### Company Organization.

The organization is divided into different departments, each department having its separate head. The lines of distinction are clearly drawn, there is no overlapping of authority, and each head is directly responsible for the work of his own department.

The sub-divisions are as follows:

Mill Superintendent, who has charge of the mill and assay office.

Mine Superintendent, who has charge of the mine.

Mechanical Engineer, who has charge of all surface labor, power house, machine shope, boiler shop, blacksmith shops, all repair work, construction work, electricians and mechanical draughtsmen.

Mine Engineer, who has charge of surveying, sampling and diamond drilling and geological work, and who is responsible for the proper compilation of data regarding ore reserves, etc.

Chief Clerk, who has charge of the accounting and time-keeping departments and of stores.

Steward, who has charge of the bunk houses, mess houses, clubs and company store.

All these departments are directly responsible to the general superintendent, and in this way the maximum of efficiency is obtained.

The Canadian Mining & Exploration Company, at the head of which is Mr. W. W. Mein, has been appointed consulting engineers.

The property is well equipped with machine and repair shops, and has a plant of sufficient capacity to generate power for all purposes. Hydro-electric power from Waweatin Falls will, however, be available in a short time, and when this is in use, costs will be materially reduced. Brick buildings for the accommodation of the men and the staff have been constructed, and a very complete hospital is also available.

# PROGRESS ON THE METALLURGY OF COPPER DURING 1911.

Written for the Canadian Mining Journal by George A. Guess.*

Copper metallurgy during the year 1912 has been stimulated by a steadily increasing price for copper. The price of the metal had remained low since the slump in 1907 until December, 1911, when it began to recover and during the present year it has steadily increased from fourteen cents in January to seventeen cents in June, remaining slightly above that figure for the balance of the year. This increased price of copper enhances the value of the output for 1912 over the year 1911 upwards of $50,000,000.

The present year has seen a growth of reverberatory furnace rather than blast furnace smelting. The increasing tonnages of concentrates, particularly in the southwest, have demanded the construction of more reverberatory furnaces. The time has gone by for the smelting of this fine material in blast furnaces. The new reverberatory plant of the Ray Consolidated at Hayden, Arizona, was in commission in May, and will handle the product from their large concentrators. The smelter at Humboldt, which consists largely of reverberatories, resumed operations in February. The Copper Queen put two oil-fired reverberatories in operation during the year, after spending some time investigating other methods of handling fines. The new plant of the Calumet and Arizona at Douglas will have four large reverberatories. The fact is realized that fine ore is a detriment to blast furnace operations, taking more coke, running more slowly, and producing quantities of flue dust. The practice, therefore, of screening blast furnace ores is becoming general. These fines, together with the flue dust, are smelted in reverberatories where their quantity is sufficient to justify such a furnace or sintered for blast furnace treatment when the tonnage is small. The Canadian Copper Co. at Copper Cliff has during the year added two large reverberatories to their smelting plant. These handle fines and flue dust and converter slag. On account of the basicity of the charge these large reverberatories have a hearth and side walls of basic brick. These are the first reverberatories to be designed and built for the burning of pulverized coal. Previous experiments in firing reverberatories with pulverized coal have been adaptations to existing construction.

Reverberatory furnaces show little change in construction. The limit of size appears to have been reached. The front of the furnace is now, however, usually built straight into the flue. The skimming is done at the side near the front.

For roasting sulphide fines for reverberatory smelting the Macdougall type of roaster continues in favour. Larger sizes, however, are being used and the rabble arms have been speeded up to twice their former speed resulting in greatly increased capacity. Roasting furnaces that have been developed in the sulphuric acid industry have entered the field of copper smelting. Herreshoff furnaces are being installed at the C. & A. at Douglas. Wedge furnaces have been put in at Braden, Copper Cliff and other places. Bedding of the charge that has proved advantageous to blast furnace operations is being adopted for fines for reverberatory smelting, and should result in greater uniformity of work and capacity, in their operation. The handling of the Miami concentrates (which consist of silica, copper, and sulphur, with practically no iron) continues to be a unique as well as successful operation. These concentrates are treated at Cananea and are blown into the converters. The construction of a suitable dust chamber for the converter gases has been found necessary.

The Canadian Consolidated Co. at Trail has changed the practice of granulating and roasting the low grade copper matte, high in gold values, and is smelting it direct with silicious ores in the blast furoace. A wide blast furnace has been developed at Great Falls. This is 84 inches wide at the tuyeres and in cross section looks like an early form of iron blast furnace. The upper tier of jackets conveying at the top. By using a slotted tuyere 3 in. x 11 in. with the long axis vertical 120 square inches of tuyere area are obtained per foot of furnace length. This is about three times the tuyere area of an ordinary blast furnace. Blast furnaces 72 inches wide at the tuyeres give improved running at Cerro de Pasco. The new blast furnace plant of the Mason Valley mines was blown in early in January.

Very considerable strides have been made in the development of basic converting during the year. The use of a basic lined converter is now almost universal. The long barrel form of the Peirce-Smith up to 37 feet in length as at Copper Cliff, has been the general form installed until this year when the form developed at Great Falls has found tremendous favour and has been installed generally in the southwest at Cananea, at the Copper Queen, and at the C. & A. at Douglas. This

*Professor of Metallurgy, University of Toronto.

form is a development of the Parrot type of converter, and has been formed to give astonishingly long life to a lining over 12,000 tons of copper have been made from one lining. The charges on this form are smaller and are finished on each shift. The Peirce-Smith takes a big charge, and twenty-four hours or longer to finish. The size of the tuyeres has been increased and their number doubled, fifteen one-inch tuyeres being increased to 34, 1 3-inch tuyeres for a 12-foot diameter converter. In addition to the two large types, many plants have lined their old acid shells with magnesite brick and are using these very successfully.

The neutralization of smelter smoke has made little progress throughout the year. The Balaklala smelter in which the Cottrell process was installed, remains closed. The Mammoth smelter at Kennet, where the Sprague process (neutralization of sulphuric anhydride with zinc oxide and baghousing the gases) has been installed, is in operation; but a new association of Shasta county farmers was formed in December to renew the fight against the smelting company. The Thiogen process of Prof. Young is still in the experimental stage. Experiments have been conducted at the Penn Smelter at Campo Seco, Cal. This process reduces the oxides of sulphur to metallic sulphur by means of volatile hydrocarbons. The two smelters in Tennessee continue to produce sulphuric acid. The output of the Tennessee Copper Co. exceeds 500 tons of 60 deg. Beaume acid per day. Despite this production of acid the company was not free from claims for smoke damage. It would appear, therefore, to be an almost impossible matter to protect vegetation from damage by smelter smoke even when the location of the plant makes it possible to manufacture from it sulphuric acid and find a market for the acid. Unfortunately, Canada has a very limited market for sulphuric acid. The average daily production of acid in Canada does not exceed 75 tons; whereas the production in the United States is upwards of 10,000 tons per day. Fortunately in Canada we hear very little complaint against the smelters on account of smoke. The smoke is recognized as a necessary evil. The short-sighted policy pursued in California has resulted in the permanent closing of some plants that afforded the only market the farmers had. They then tried to undo the damage they had done by urging the resumption of smelting operations.

The last few years has seen wonderful tonnages of low grade copper ores handled in wet concentration plants, particularly in Utah and Arizona. The extraction is, however, extremely low, being more often under 70 per cent. than over. This tremendous waste has turned attention to wet methods of treating low grade copper ores. Although there has not been any great progress made during the year, there are at the present time a great many companies investigating various processes. In fact, all the larger copper companies in the United States are experimenting for the wet treatment of their low grade ores. The Anaconda Company has been investigating the Bradley process. The Copper Queen has two men who have spent much time in copper leaching experiments investigating their possibilities. The Braden Copper Co. is experimenting in the leaching with sulphuric acid made from the roasting of their concentrates.

It is quite likely that the next two years will see some new developments in the hydrometallurgy of copper. Nothing new has been given out during the year regarding the progress made by the Bradley process in treating the Anaconda slime accummulation. Such has been found extremely difficult to do anything with, and if Mr. Bradley can work out the successful treatment of slime he will find many applications for his process.

# THE COAL TRADE OF NOVA SCOTIA IN 1912.

A Resume by F. W. Gray.

The year 1912 presented no outstanding features of interest concerning the coal mines of Nova Scotia, with the notable exceptions of the increase in production and a large capital expenditure on new mines and equipment.

As far as can be estimated at the time of writing, the coal output of the Province will approximate 6,900,000 tons, an increase over 1911 of 650,000 tons.

Cape Breton mined 5,650,000 tons, or 82 per cent. of the entire tonnage. The combined output of the collieries controlled by the two large Cape Breton companies, the Dominion Coal Company and the Nova Scotia Steel & Coal Company, accounts for 5,770,000 tons, or 84 per cent. of the provincial output. The Dominion Coal Company's collieries in Cape Breton and on the mainland put out a total of 4,934,000 tons, or 72 per cent. of the entire Nova Scotian output.

The whole, and more, of the total increase in outputs over 1911 has come from the properties operated by the Dominion Coal Company, who exceeded the 1911 production by 683,000 tons, comparing with the total provincial increase of 650,000 tons.

Considering the large capital expenditure that has been made on coal mines in Nova Scotia, the increase in production is not any greater than it should be, and if a comparison is made with the United States the insignificant character of the increase becomes plain. On the authority of the "Coal Trade Journal" the coal production of the United States in 1912 was 540,000,000 tons, being 40,000,000 tons greater than the high mark of 1910. The mere increase in the United States output is, therefore, almost four times greater than the entire annual coal output of Canada.

It does not appear probable that 1913 will see any very remarkable rise in the outputs of the Province. It may be anticipated that the Dominion Coal Company will again provide the greater portion of the additional tonnage; and the Acadia Coal Company will probably reap the benefit of their large capital outlay in 1911 and 1912. The development of the new openings which it is understood are projected at the mines of the Nova Scotia Steel & Coal Company, and by the Inverness Coal & Railway Company at Inverness, will not add greatly to production until 1914.

The general prosperity of the coal trade during 1912 was helped by the coal shortage occasioned by the English coal strike and the anthracite strike in the United States. In the spring there was a brisk demand for bunker coal, and a good deal of Nova Scotian coal found its way into ports usually supplied from British mines. The steady growth of manufacturing concerns around Montreal, and the opening up of the eastern sections of the new transcontinental lines is creating a healthy demand for soft coal in the natural market of Nova Scotia.

**Walker ventilating fan and fire-proof House—Dominion No. 14 Colliery.**

There were no accidents during the year involving serious loss of life. So far as it is possible to ascertain the fatality rate will be less than that of 1911, probably about 2.5 per thousand employed.

The Commission appointed by the Nova Scotia Government to investigate the flooding of the Port Hood Colliery completed its work during the year, and it is expected that the report will be made public when the Provincial Legislature assembles in the spring. There have been no new developments in this matter during the year.

The Morien Colliery, previously operated by the North Atlantic Collieries Company, was dismantled and abandoned during the summer of 1912.

The Broughton Colliery, situated near the fringe of the Morien Basin of the Sydney coalfield, about three miles from No. 21 colliery of the Dominion Coal Company, and owned by the Cape Breton Coal, Iron & Railway Company, has been idle since 1907. At the present time some activity is being shown, and it is understood a coal-shipping pier is to be erected on Mira Bay, and a railway branch of four miles in length is to be constructed connecting this pier with the mine.

The promoters and officers of the Cape Breton Coal, Iron & Railway Company are all reputable Englishmen connected with coal mining in Great Britain, and are themselves largely interested financially. The prospectus of the Company as advertised in England was decidedly roseate, and if the results therein forecasted are obtained, it will surprise disinterested local mining men, who are in a position to judge from their own experience. Under the circumstances, the writer prefers not to hazard a prediction as to whether the Broughton mine will become an important factor in coal production in 1913, or not.

Following is a tabulation of the outputs of the principal operating companies in Nova Scotia. The figures are only approximately correct, accurate tonnages not being available at the time of writing. There is much ambiguity about figures of Nova Scotian coal outputs, as some returns deal only with sales, and others follow the Government year which ends on September 30th.

| | Outputs 1911 Tons 2240 lbs. | Outputs 1912 Tons 2240 lbs. |
|---|---|---|
| Dominion Coal Company— | | |
| Glace Bay mines | 3,985,000 | 4,514,000 |
| Springhill mines | 266,000 | 420,000 |
| Nova Scotia Steel & Coal Co. | 780,000 | 842,000 |
| Acadia Coal Company | 370,000 | 433,000 |
| Intercolonial Coal Company | 263,000 | 236,000 |
| Inverness Coal Company | 291,000 | 280,000 |
| Maritime Coal Company | 160,000 | 120,000 |
| Colonial Coal Company | 30,000 | 35,000 |
| Others | 105,000 | 50,000 |
| | 6,250,000 | 6,930,000 |

The Nova Scotia Steel & Coal Company exceeded their 1911 tonnage by 62,000 tons. The output therefore comes back to the same level as in 1910. This company have not made any important additions to their colliery equipment during the year, but it is understood a new shaft is projected in the near future.

The Acadia Coal Company increased its output to 433,000 tons, although, during the concluding months of the year the operations of the company have been hindered by disagreement with the workmen as to hours of work on Saturdays.

During the year the new central power plant at the Allan shaft was completed, which is intended ultimately to provide electric drive for both the Allan shaft and the rejuvenated Albion mine. At this last named colliery a new steel bank-head has been erected and a complete electric equipment, including fan, compressors, screening plant and underground pumps. At the Allan shaft a high-duty steam-driven hoisting engine is being installed, with which it is expected to hoist four-deck cages from No. 1 shaft.

A full description of the new equipment of the Acadia Coal Company was given in the special Nova Scotia edition of this Journal, as was also a detailed account of the Nova Scotia Steel & Coal Company's coal mines, so that it is unnecessary to say more in this article.

The Acadia Coal Company has carried out extensive diamond drill prospecting during the year, having put down bores over 2,000 feet in depth. The company is also unwatering the Ford seam and energetically developing its properties in general.

The Intercolonial Coal Company show a small falling off in their output. The management hope, however, to recoup the decrease in 1913.

The output of the Inverness Coal Company shows a decrease of 12,000 tons, which was partly caused by labour troubles. A Conciliation Board was appointed by the Government to consider and adjust these complaints, which was done in a manner satisfactory to all concerned. It is the intention of the management to instal a new and more powerful hoisting engine. The coal has now to be hauled a distance of 6,000 feet from the deep and the present engine is too light for the work. It is expected to have the new engine ready for work against the opening of navigation in the spring. In the near future the management intends to sink a slope on the 13-foot seam, which overlies the 7-foot seam now being worked.

The Maritime Coal Company produced less coal than in 1911, and they have added no new equipment.

Mention may also be made of the Colonial Coal Company, whose mine is situated between North Sydney and Sydney Mines. This company, although only operating on a small scale, has introduced a commendable innovation in a briquetting plant. The coal produced by this company's mine would not stand exposure to the weather or transportation, and quickly became slacky. To get over this difficulty, the management decided to briquet the coal, and they have succeeded in producing a product which has met with considerable local demand. It will not be surprising to hear of some of the larger coal companies in Nova Scotia following the example of the Colonial Coal Company. The modern briquetting plant is a great advance over the old-fashioned machine, which produced a large "brick," to consolidate which it was necessary to use an undue quantity of pitch. The plant of the Colonial Coal Company turns out a briquette about the size of a goose egg, hard and polished, and capable of standing transportation.

The Dominion Coal Company had a particularly successful year. The output of the Glace Bay collieries was approximately 4,514,000 tons, comparing with 3,984,749 tons in 1911, an increase of 530,000 tons. Following is a comparison of the outputs by collieries:

| | 1911 (tons) | 1912 (tons) |
|---|---|---|
| No. 1 | 577,405 | 585,000 |

No 1 colliery had the largest output since 1902, the year immediately preceding the fire that occurred in this mine. Nos. 2, 6, 7, 9 and 10 collieries all produced the largest tonnage in any year. The most striking increases, however, are naturally in the new mines of the Waterford district, and at Birch Grove. The combined increase of the Waterford collieries over 1911 amounts to 410,000 tons, and the Birch Grove collieries, of course, show much larger tonnages. The major portion of the Coal Company's increase over 1911—ninety per cent. to be exact—comes from the new collieries 12 to 22 inclusive. The only collieries showing a decrease are Nos. 3, 5 and 8, these three mines being old collieries approaching the stage of small production preceding exhaustion. Old mines, however, like King Charles, are often a long time a dying. A point of interest in connection with the older collieries of the Dominion Coal Company is that they are all on the upper and thicker seams first attacked, so that the plant

**Slopes and temporary Bankhead arrangements—Dominion No. 22 Colliery.**

and shafts can be utilized for the mining of the lower seams, as yet practically virgin.

The Coal Company has made very large additions to their equipment during 1912. As these were described by the writer in more or less detail in the special Nova Scotia edition of the Journal, published in September, a brief recapitulation will suffice.

At No. 2 colliery a large Walker ventilating fan, with adequate concreted surface airways was installed. This fan is to be used only as a spare or emergency fan, and is entirely additional to the ordinary ventilating machinery of the mine.

No. 14 colliery was provided with a permanent electric coal hoist, already fully described in the columns of this Journal. Since installation the hoist has worked continuously and satisfactorily.

At No. 15 colliery the permanent bank-head was completed, together with all the surface erections. The permanent coal hoist will be installed next spring, and like No. 14 hoist, will be electrically operated.

hoist and colliery buildings were all completed. The construction of the bank-head at No. 22 colliery is proceeding, and this colliery will be equipped to the full producing stage in 1913.

It is also probable that the Coal Company will reopen the Emery seam near the present No. 3 colliery. Slopes were driven here from the outcrop of the Emery seam in 1899 for a length of 1,600 feet, and were temporarily abandoned in 1901. The existing plant and bank-head at No. 3 colliery will be utilized for the reopened slopes, to which the name of Dominion No. 11 colliery will be given.

By the early summer of 1913 the Coal Company expects to have sixteen collieries in full operation, with complete equipment, and to have Nos. 11 and 17 collieries well under way.

Unless the unforeseen intervenes, the outputs and shipments of the Coal Company in 1913 should be even larger than they were in 1912. The mines will work steadily all through the winter, so far as the weather

**Mouths of Slopes, Compressor House and Bankhead—Dominion No. 21 Colliery.**

The erection of the colliery buildings is proceeding at No. 16, and brick is being used instead of wood, a commendable departure. Although this colliery is producing up to one thousand tons daily, the equipment is as yet of the most temporary character. The permanent bank-head is under construction and will be completed in the early summer of next year.

An electric power transmission line has been run to the site of the old Victoria mine, which it is the intention of the company to unwater and re-open for work as soon as possible. Electrically driven centrifugal pumps are being set up at the present time. The work of rehabilitating the underground workings will be proceeded with as the water in the mine is lowered. This colliery was closed by the Coal Company in 1897, and in that year produced over 100,000 tons. It is expected that it will be possible to obtain a considerable output from the workings quickly, as the territory will not require to be developed as in the case of an entirely new mine. The coal taken from the Old Victoria slopes had an excellent reputation for quality.

At No. 21 colliery, the premanent bank-head, coal

permits, and a larger quantity of coal will be stocked during the season of closed navigation than in any previous winter season. Although it is not considered good form to prophesy regarding coal outputs, it is not unreasonable to anticipate an output from the Coal Company's Glace Bay mines of from 4,700,000 to 4,800,000 tons during 1913.

A new electric generating station to serve the Waterford collieries has been partly completed, the first electrical unit having been installed. The Bettington boilers are under steam, and power is being generated to supplement the current generated at the No. 2 power house.

In the Waterford and Birch Grove districts the company has made large expenditures on dwelling house accommodation for its work people, and has also installed extensive water systems for supplying the collieries, for fire protection, and the domestic requirements of the colliery towns. The company is also supplying electric light and power to the large population that has been attracted by the mining developments.

At Sydney a Baum coal washer was completed and put into operation, and reinforced concrete storage hoppers are being constructed to hold 6,000 tons of washed slack. They will be completed in the spring.

The new coal-shipping pier at Sydney is completed, except for the fittings, and will be ready to ship coal when navigation opens in the spring.

The increased output of the company has necessitated large additions to the rolling stock and motive power of the Sydney & Louisburg Railway, and the construction of additional branch lines and sidings, and passenger and freight accommodation. Extensions have been made to the car repair shops, machine shop, mine car shops, etc., and a large brick building has been provided for safe storage of patterns, the company's stock being both extensive and peculiar, and of course very valuable.

The Springhill mines steadily improved in outputs throughout the year, producing about 420,000 tons, compared with 266,000 tons in 1911.

The output for December was lessened by a fire that occurred in the No. 2 mine on Christmas Eve. The district affected by the fire was speedily isolated by concrete stoppings, and it is expected that mining operations in the No. 2 mine will have been resumed early in the New Year.

During the year the only additions to the existing equipment were a miners' wash house and a rescue station, equipped with the regulation Draeger apparatus and accessories.

Diamond drill prospecting has been carried along for some time past, and in all probability a new slope will be opened out early in 1913.

The Dominion Coal Company Employees' Benefit Society is becoming an important organization, and reflects the great expansion of the Coal Company's operations. The society was inaugurated in July, 1910, with a membership of under 7,000, and at the close of 1912 the membership numbered 11,120 persons. The income of the society in 1912 was approximately $144,000, $63,000 being contributed by the company, $11,500 by the Government of Nova Scotia, and $6,250 from interest on investments.

The expenditure totalled $98,600, of which amount $69,000 was paid out for weekly indemnity for disability caused by sickness and accident. For death claims $7,600 kas paid, and to widows and children $16,700, making a total paid out to dependents of deceased members of $24,300. At the end of the year there were dependent on the funds of the society, 86 widows and 293 children, an increase from the end of 1911 of 33 widows and 55 children.

The year was a disastrous one to shipping engaged in the coal trade. The "Bonavista," after a long career in carrying coal and passengers, became a total wreck in the Bay of Fundy.

The "Isleworth" was lost in the drift ice off the Nova Scotia coast in the spring, and the "Helvetia" was sunk in a collision with an "Empress' steamer in the St. Lawrence.

The "Gladstone" went aground below Quebec and was badly damaged. In none of these accidents was there any loss of life.

The "Morien" left Louisburg for Newfoundland in the middle of November and was lost with all hands, it is presumed, off Placentia Bay. A collision occurred between two "Black Diamond" boats in Sydney Harbor, which caused the loss of five lives.

Among publications of the year bearing on coal mining in the Province may be mentioned the report of Dean Fernow, of Toronto University, on "Forest Conditions of Nova Scotia." This report is the result of a reconnaissance survey of the Province, the expense having been defrayed by the Government of Nova Scotia, who allowed the report to be made public at the request of the Commission of Conservation. The supply of pit timber is becoming one of the problems of mining, even in Nova Scotia, and Dr. Fernow's report contains matter of considerable significance to colliery owners. Dr. Fernow states the forest resources of Scotia are "in danger of exhaustion within the next two decades," although they are capable under proper management "of forever producing, by annual increment, as interest, at least twice as much as is now being cut from capital stock."

The report corrects some popular misconceptions as to the rate of growth of forest trees, and points out that from 140 to 150 years is required to grow trees suitable for lumbering. One-fourth of the forest area of the Province is semi-barren of commercial trees because of repeated fires, and under the most favourable conditions of planting and exclusion of fires, these barrens could not be made to produce a marketable forest under at least one hundred years.

It is to be expected that Dr. Fernow's recommendations will lead to a more intelligent forestry policy in Nova Scotia, a matter in which the co-operation of the mining societies and colliery companies could doubtless be usefully enlisted.

Accompanying the report is the only small-sized coloured geological map of Nova Scotia the writer has yet seen. If a similar map were to accompany the Nova Scotia Mines Report, soon to be issued, it would be much appreciated.

Another publication containing a great amount of valuable data regarding Nova Scotian coals is "An Investigation of the Coals of Canada," prepared under the direction of Dr. Porter of McGill University, and published by the Government at Ottawa. Three out of six volumes are already issued. The work is encyclopaedic in its scope, and is strikingly illustrated.

The visit of the delegates to the Intefnational Geological Congress promised for the summer of 1913 is looked forward to with considerable interest, and it goes without saying these gentlemen will receive a warm welcome, and in addition will find many points of interest in our coal strata exposures and in methods of coal extraction in Nova Scotia.

## WAGES PAID IN ALBERTAN COLLIERIES.

From Annual Report of Department of Public Works.

The scale of wages paid in the Province at the end of the year 1911 shows increases over the wages paid in previous years.

The general wage schedule now being paid for day labour is as follows:

**Outside Wages.**

| | Per day. | Hours. |
|---|---|---|
| Fire bosses | $110.00 to $115.00 per month | |
| Bottom man | $2.89 | 10 |
| Slate pickers, boys | 1.37 | 10 |
| Slate pickers, men | 2.47 | 10 |
| Car oilers, men | 2.47 | 10 |
| Car oilers, boys | 1.65 | 10 |
| Tally boys | 1.37 | 10 |
| Teamsters | 2.89 | 10 |
| Blacksmith | 3.85 | 10 |
| Blacksmith's helpers | 2.90 | 10 |

| | | |
|---|---|---|
| Power house engineers | 3.85 | 12 |
| Power house engineers | 3.40 | 8 |
| Fan men | 2.90 | 12 |
| Hoisting engineers | 3.20 | 8 |
| Hoisting engineers | 3.78 | 10 |
| Hoisting engineers | 4.40 | 12 |
| Tail rope engineers | 3.63 | 8 |
| Tail rope engineers | 3.85 | 10 |
| Endless rope engineers | 3.30 | 10 |
| Box car loader engineer | 3.40 | 10 |
| Tipple engineer | 3.40 | 10 |
| Screen engine tender | 2.65 | 10 |
| Locomotive engineer | 3.40 | 10 |
| Locomotive switchman | 3.00 | 10 |
| Fireman | 2.89 | 8 |
| Fireman | 3.85 | 12 |
| Fireman's helper | 2.65 | 10 |
| Railway car helper | 2.60 | 10 |
| Tipple dumper, man | 2.89 | 10 |
| Tipple dumper's helpers | 2.64 | 10 |
| Tipple dumper, boy | 1.65 | 10 |
| Top eagers | 2.64. | 10 |
| Car repairer | 3.40 | 10 |
| Car repairer's helper | 2.90 | 10 |
| Breaker engineer | 3.40 | 10 |
| Fan fireman | 3.40 | 12 |
| Lampman (depending upon number of lamps and skill of man) | $2.47 to 2.89 | 8 |
| Lampman (depending upon number of lamps and skill of man) | $2.47 to 3.40 | 12 |
| Machinists | $3.40 to 3.85 | 10 |
| Machinists' helper | 2.90 | 10 |
| Ashman | 2.50 | 10 |
| Ashman | 2.89 | 12 |
| Wiper, man | 2.89 | 12 |
| Coupler, man | 2.47 | 10 |
| Coupler, boy | 1.65 | 10 |
| Breaker oiler | 2.89 | 11 |
| Washer or tipple oiler | 2.89 | 11 |
| Breaker picker boss | 2.89 | 10 |
| Timber framer | 3.40 | 10 |
| Timber sawyer | 2.64 | 10 |
| Box car shoveler | 2.89 | 10 |
| Breaker platform boss | 2.89 | 10 |
| Breaker platform men | 2.60 | 10 |
| Breaker screen men | 2.47 | 10 |
| Rock bank men | 2.47 | 10 |
| Dirt bank men | 2.47 | 10 |
| Finisher after box car loader | 2.47 | 10 |
| All other outdoor labour | 2.47 | 10 |

**Bee Hive Coke Ovens.**

| | |
|---|---|
| Levelling and drawing (6½ ton charge), per oven | $1.00 |
| Levelling and drawing (5-ton charge), per oven | .80 |
| Loading into box or open cars (over 200 tons per month), per ton | .17 |
| Loading into box or open cars (less than 200 tons per month), per ton | .16 |

| | Per day. | Hours. |
|---|---|---|
| Steam locomotive engineer | $3.40 | 10 |
| Motorman | 3.18 | 10 |
| Larryman | 2.47 | 10 |
| Plasterers | 2.47 | 10 |
| Carters and cleaners | 2.47 | 10 |
| All other labour | 2.47 | 10 |

**Belgian Coke Ovens.**

| | | |
|---|---|---|
| Ram engine man | 3.40 | 10 |
| Chargers | 2.89 | 10 |
| Clayers | 2.89 | 10 |
| Drawers | 2.89 | 10 |
| Loaders | 2.60 | 10 |

**Briquette Plant.**

| | | |
|---|---|---|
| Engineer | 3.86 | 12 |
| Briquetter | 3.97 | 12 |
| Briquetter's helper | 3.40 | 12 |
| Tar Melter | 2.89 | 12 |
| Labourers | 2.89 | 12 |

**Inside Wages**

| | | |
|---|---|---|
| Shotlighter | 3.30 | 8 |
| Bratticemen | 3.30 | 8 |
| Bratticeman's helper | 2.75 | 8 |
| Timberman | 3.30 | 8 |
| Timberman's helper | 2.75 | 8 |
| Tracklayers | 3.30 | 2 |
| Tracklayer's helper | 2.75 | 8 |
| Motorman | 3.05 | 8 |
| Motorman's helper | 2.75 | 8 |
| Locomotive engineer | 3.05 | 8 |
| Locomotive switchman | 2.75 | 8 |
| Drivers | 3.03 | 8 |
| Drivers, wet places | 3.30 | 8 |
| Drivers, spike team | 3.50 | 8 |
| Couplers, men | 2.75 | 8 |
| Couplers, boys | 1.65 | 8 |
| Switch boys | $1.37 to 1.65 | 8 |
| Door boys | 1.10 | 8 |
| Rope riders | 3.03 | 8 |
| Main and tail rope riders | 3.30 | 8 |
| Pushers | 2.75 | 8 |
| Buckers | 2.75 | 8 |
| Loaders | 2.75 | 8 |
| Miners | 3.30 | 8 |
| Miners, wet places | 3.75 | 8 |
| Rock miners | 3.75 | 8 |
| Timber handlers | 3.03 | 8 |
| Labourers | 2.75 | 8 |
| Cagers, slope and incline | 2.75 | 8 |
| Cagers, shaft | 3.30 | 8 |
| Machinemen | 3.75 | 8 |
| Machinemen's helper | 3.30 | 8 |
| Pumpmen | 2.75 | 8 |
| Pumpmen (A. R. & I. Co.) | 3.20 | 8 |
| Hoistmen | $3.03 to 3.30 | 8 |
| Drivers, boys | $1.65 to 2.75 | 8 |
| Grippers | 2.75 | 8 |
| Grippers, boys | $1.65 to 2.75 | 8 |
| Pipe fitter's helpers | 2.75 | 8 |
| Pick carriers | $1.35 to 2.75 | 8 |
| Clutchmen | 3.30 | 8 |
| Rollermen | 2.75 | 8 |

Miners on contract average from $3.50 to $6.00 per day of eight hours.

With the number of railways which are now being built and also those that are projected in all parts of the Province, the future of the coal trade for both steam and domestic coal can now be looked forward to with confidence, and although the output is increasing rapidly, the market appears to be increasing as rapidly. These new railways are not only the means of bringing new settlers into the Province, but are also the means of allowing coal to be transported to those districts where before it could not be obtained.

# THE YEAR IN ONTARIO.

By Thos. W. Gibson, Deputy Minister of Mines.

The year 1912 was probably the best that the mining industry in Ontario has yet seen. Not only have all the active mining camps been operating steadily and at a high rate of production, but in what is perhaps the most important camp of all—the Sudbury Nickel region—development work has revealed large reserves of ore, previously not known to exist.

Metalliferous mining has come to be so largely predominant in Ontario that the condition of this branch determines the condition of the industry as a whole, hence it is satisfactory to be able to say that in all the five metals which the mines of the Province yield in quantity, namely—silver, gold, iron, copper, and nickel, the situation and outlook has never been better.

## SILVER.

The mines of Cobalt may have reached their apogee, but they are still yielding about one-seventh of the world's production. In 1911, the output was 31,500,000 ounces, worth sixteen million dollars. In 1912, the figures when compiled will probably show a decrease in production of a million or a million and a half ounces, but this falling off is more than compensated for by a larger return for the year's yield, which was worth two and one-half or two and three-quarter millions of dollars more than in 1911, the average price of silver having gone up to a little over seven and one-half cents per ounce as compared with that year. Thus on a lessened output the dividend paying companies have been put in a position to make a larger distribution of profits.

The natural effect has been to stimulate interest in the Cobalt camp, and this effect has been increased by several interesting developments. One of these was the location by the Seneca-Superior Company of a first-class vein carrying high grade ore in the bottom of Cart lake. This lake occupies a depression in the conglomerate, here say 300 feet thick, and the vein was found by a cross-cut which was being driven across the lake bed. The property is held by the Seneca-Superior Company upon a lease from the owners, the Peterson Lake Company. A striking of rich ore by the Casey Cobalt mine on an outlier of conglomerate, some fourteen or fifteen miles away from Cobalt proper, shows the potentiality of that formation and the advisability of searching every square yard of it. Another event of some importance is the finding of good ore by the Beaver mine in the diabase underlying the Keewatin, though actual quantities have not yet been proven.

The history of any mining camp, so far as individual properties are concerned, is usually a checkered one; some mines improve with age, others pass quickly. The Nipissing, with its over-shadowing area, retains the lead in production; the Coniagas, with an occasional carload of rich ore and its steady outpour of concentrating rock, is followed closely by the La Rose, the oldest mine in the camp, by McKinley-Darragh-Savage, whose career has been one of striking success, and by the Crown Reserve whose little patch of 22 acres beneath the waters of Kerr lake, has been a veritable cave of riches. Buffalo maintains its position well, and the recrudescence of Cobalt Townsite was one of the features of the year. Temiskaming and Beaver, taken together, upheld the credit of southeastern Coleman, and Cobalt Lake reduced its output, and so, materially, did O'Brien, while Hudson Bay, in the extreme north of Coleman, slackened its pace. Trethewey also fell off, and Right of Way produced but little. In South Lorrain, Wetlauffer did fairly well, and in Gowganda, Miller Lake-O'Brien continued production from its veins in the diabase, and Mann Mines also began to yield. Millerett has been treating chiefly low grade ore.

The camp is making large strides in refining the ores on the spot. The Nipissing mill for high grade ore scored a decided success in metallurgical practice. With separate plants for treating high grade and low grade ore nothing now leaves the Nipissing except in the form of bullion. This is also practically the case with the Buffalo, and concentrating plants for low grade ore are numerous. One effect of this tendency is to cut down the shipments of ore and concentrates by rail, but it is all in the direction of larger profits.

An event of moment was the construction of the Temiskaming & Northern Ontario branch railway from Earlton to Elk lake. This has given a noticeable impetus to the development of a number of properties in that district, including the Donaldson (purchased by the Beaver Company), Beacon, Hitchcock, etc.

There were no labour troubles at Cobalt during the year, and little difficulty with hydraulic power.

## GOLD.

The Porcupine camp came into production during 1912, 40 stamps being in operation at the Dome mine, and 40 at the Hollinger. Smaller contributors were the McIntyre and Vipond. The yield of gold for the year was about two million dollars. A little of this came from mines in other districts, principally the St. Anthony at Sturgeon Lake, and the Cordova in Hastings county, but the bulk was from Porcupine. Interest is naturally great in the Hollinger mine, which began the payment of dividends in November, announcing the intention of making a distribution of profits every four weeks. No. 1 vein, which showed at the 100-foot level, a length of 1,000 feet, with a width of 8 feet, and \$31.54 of gold per ton, has been developed for a length of 839 feet. At the 200-foot level, where the width is 6.7 feet, it shows contents of \$45.74 per ton. This vein has been developed for 63 feet at No. 3 level, at which point it had a value of \$8.40 per ton. Under date of October 5th, General Manager P. A. Robbins, reported that up to that time 20,444 tons of ore from development, partly made up of waste rock inadvertently included from drifting and sinking, had been milled, and had shown an average value of \$19.70 per ton. Ore from stopes to the extent of 5,777 tons had been treated and had shown an average value of \$37.89 per ton. The average value of all ore removed from the mine up to that time was \$23.69 per ton, established by treating 26,221 tons of ore. The mill has been a success, inasmuch as while designed to handle 300 tons of ore per day, from 450 to 500 tons can be put through. Extraction from \$30.00 ore is 97 per cent.

Details have not yet been published as to the results at Dome, but it may be surmised that these have been satisfactory. Work here is entirely open cut, and schist as well as quartz is put through the mill.

Progress at Porcupine was impeded by a labor strike which broke out about the middle of November. The men refused to accept the proposed cut in wages which the mine owners claimed was justified by the reduction of living expenses consequent upon the introduction of the railway, and which left the scale at higher than the Cobalt rate. The close of the year saw the strike still unsettled, but apparently with a large number of miners leaving the camp and the fortunes of war in favour of the mine owners. The camp has at present a capacity of about 100 stamps, which will be added to during 1913, and a substantial production of bullion may be looked for.

The other gold districts, such as Swastika, Munro, Larder Lake, etc., witnessed considerable activity during the year, but in none of them has production yet been established on a permanent basis.

### IRON.

1912 was not conspicuous by a large production of iron ore, the Helen mine at Michipicoten being practically the only shipping mine. Developments of significance, however, were in progress on other properties, notably at Moose mountain and Magpie. At the former, a Gröndal concentration plant has been installed and is now practically in readiness to make shipments of briquettes containing 63 per cent. iron, and within the Bessemer limit for phosphorus and sulphur. At Magpie, a roasting equipment is nearing completion, costing perhaps $1,000,000. The object of the process is to eliminate the sulphur and carbon dioxide from the ore, which is largely sideritic. It is to be hoped these pioneer processes will justify themselves by their results, and so show the way for the utilization of the large bodies of low grade iron ore, chiefly magnetite, which exist in northern and northwestern Ontario.

### NICKEL AND COPPER.

The nickel mines of Sudbury now easily dominate the production of this metal for the world. Extensive boring by the diamond drill were made during the year, which show that the bodies of ore yet to be mined are very large. The Canadian Copper Company has proven the Frood, or No. 3 Mine, to contain many millions of tons, and though the nickel contents are not so high as at Creighton, the quantity of ore is said to be greater. It is stated that this company contemplates the enlargement of its mining and smelting operations to an extent that will enable it to handle 5,000 tons of ore per day. The Canadian Copper Company's existing smelting facilities were improved by the substitution of basic for acid converters and the introduction of reverberatory furnaces. The Mond Company had drills on the Frood Extension, and found the Frood orebody to cross their line at a depth of 600 feet. This company's new smelter at Coniston will be ready for operation in 1913. The Dominion Nickel Copper Company purchased the old Murray mine, formerly owned by the Vivians, who worked it for a number of years, since when it has been idle. This company has also bought the Gertrude and Elsie mines, owned by the Lake Superior Corporation. On the Murray, it placed seven diamond drills at work, and it is said that some six million tons of ore have been located about 400 yards west of the old workings. The company has moved the site of its proposed smelter from the Northern Nickel range to Snider township, so as to be closer to its new mines. On the T. & N. O. Railway, the Alexo Nickel mine, whose ore is similar to that of Sudbury, shipped several thousand tons to the Mond smelter at Victoria Mines. The output of nickel for 1912 will be about 21,000 tons, much the largest production ever made.

Copper in Ontario is really a by-product of nickel, and its production increase or decreases with that of the latter metal. In 1912, the yield was about 11,000 tons, a record quantity. The sulphide mines of the north shore are at present idle, notwithstanding the high price of copper. Some prospecting was done on low grade bodies of copper ore near Dane, on the Temiskaming & Northern Ontario Railway.

### NON-METALS.

Southwestern Ontario yields petroleum, natural gas and salt. The petroleum wells are declining in yield year by year, and the production will certainly be less than in 1911, when it was 10,000,000 gallons. There will be an increase of ten or fifteen per cent. in the output of natural gas, as compared with 1911. The salt industry expands slowly, and has an output of about half a million dollars in value per annum. Gypsum also continues to be raised in the valley of the Grand River, but the production is not large, although stimulated to some extent by the requirements for the manufacture of Portland cement, now being made in increasing quantities. The cement industry originated with the marl deposits of Addington and Grey counties, but the tendency of recent years has been to substitute solid limestone for marl, as being cheaper and yielding a cement not inferior in quality. The production of iron pyrites promises to become important. Its chief use is in the manufacture of sulphuric acid, of which large quantities are required in the manufacturing and chemical industries. There are a number of deposits in eastern Ontario, but the largest known bodies are in the northwestern portion of the province, one of which, on Lake Minnitakie, near the Grand Trunk Pacific Railway, is now under operation. Feldspar, graphite, talc, corundum, mica, and other mineral substances continue to be raised and treated in varying quantity from year to year, and the production of these in 1912 was about normal. Building operations were active in the cities during the year, and called for large quantities of brick, stone, and lime. Fortunately the raw materials for all three exist in almost unlimited quantity, and the production was very brisk. The quarries of Bancroft yield marble of great variety of shades and markings, quite equal to almost any demand for construction and decorative purposes. As by-products of silver mining, white arsenic and the oxides of cobalt and nickel are produced in large quantities. The cobalt trade of the world is now practically supplied from the ores of the Cobalt camp.

The value of the mineral production of the province for the year 1912, computed at the point and in the form produced, will be in the neighborhood of $45,000,000.

# BOOK REVIEWS.

**Cyanide Practice in Mexico—By Ferdinand McCann—199 pages—39 illustrations and 2 folding plates—Cloth—6 x 9 in.—$2 postpaid—Published by the Mining and Scientific Press, San Francisco—1912—For sale by the Canadian Mining Journal, Toronto.**

Although in most part a series of extracts from a volume written some time ago in Spanish by Mr. McCann, there is sufficient original matter in this little book to give it distinctiveness and freshness.

Short preliminary pages are followed by descriptions of cyanide practice at eleven important Mexican plants, such as El Oro, Guanajuato Consolidated, Esperanza, etc. Mr. D. L. H. Forbes, now of Toronto, and Mr. Bernard McDonald contribute a chapter each.

The five concluding chapters take up, respectively, cyanide practice in small mills, continuous cyanide treatment in connection with the Pachuca tank, cyanidation in pan-amalgamation mills without change in the machinery, precipitation on metallic zinc, and treatment of cyanide precipitates.

Mr. McCann has paid especial attention to the cyanidation of silver ores; in fact, his book is the best source of reference that we have seen on this important subjest. The illustrations include the flow-sheets of many typical mills.

---

**Coal—Its Composition, Analysis, Utilization, and Valuation—By E. E. Somermeier, Professor of Metallurgy, Ohio State University—175 pages—Illustrated—Board covers—Price $2.—Published by McGraw-Hill Book Company, New York—1912—For sale by the Canadian Mining Journal.**

It is unfortunate that the first prefatory page of "Coal" contains an inexcusable grammatical blunder. Prof. Somermeier deliberately uses the phrase "this data." Both author and publisher are to blame for this solecism.

The purpose of "Coal" is to throw into readable shape material concerning the physical and chemical qualities of coal, and concerning, also, its uses. The chapter headings give an idea of the ground covered. They are: Composition and Heating Value, Chemical Analysis, Sampling, Methods of Analysis, Determining the Calorific Value, Summary of Chemical Records, Improvement of Coal by Washing, Purchase of Coal under Specifications, Flue Gas Analysis, and Analytical Tables. The tables include a comparison of the composition and heating value of air, dried wood, peat, lignite, bituminous coals, semi-bituminous, and anthracite. This is followed by a lengthy tabulation of the composition of typical coals from all over the United States. No Canadian fuels are touched upon. In the chapter on specification purchase, we note that the city of Toronto's standard is quoted. Here 13,000 B.T.U. is taken as a basis, with 10 per cent. ash, 2 per cent. moisture, and 1½ per cent. sulphur. Coals that do not come up to these specifications may be accepted or rejected; but, if accepted, the price is adjusted to the actual calorific value of the fuel.

"Coal" should prove a useful book, although its treatment is rather slight than otherwise.

**Building Stones and Clay Products—A Handbook for Architects—By Heinrich Ries, Ph.D.—8vo, XIII 415 pages—Fully illustrated—Cloth cover—Price $3.—Published by John Wiles & Son, New York, 1912—For sale by the Canadian Mining Journal.**

Dr. Ries is too well known to the Canadian public and to Canadian mining men to need an introduction. He has made himself a world-recognized authority on economic geology, and has devoted much time to special research in ceramics and clay products generally. Thus the reader can accept his latest book with the comfortable assurance that it is as sound and modern as it can be.

The possibilities of Canadian building stones and clay products have too long been neglected. This fact has been recognized by our Dominion Mines Branch, and that organization is collecting and distributing much valuable information. Obviously, Dr. Reis' volume has made a timely appearance. Though designed primarily for the architect, the mining man will find a fund of helpful and suggestive information within its covers.

The sequence of subjects dealt with is as follows: After treating rock minerals and rocks, and the properties of building stone, Dr. Ries takes up granites, gneisses, sandstones, limestones, marbles, slates, and serpentine. He then proceeds to discuss the the properties of clay, building brick, architectural terra cotta, structural hollow-ware, roofing tile, wall and floor tile, sewer pipe, and sanitary ware.

A sufficient geological and technical glossary is appended.

The paper used is of excellent quality, the type is clear, and the general make-up is up to high standard that one expects from John Wiley & Sons.

---

**Introduction to the Study of Minerals—A Combined Text-book and Pocket Manual—By Austin Flint Rogers, Ph.D.—522 pages—Illustrated—Soft cover—Price $4.—Published by McGraw-Hill Book Company—1912—For sale by the Canadian Mining Journal.**

Dr. Rogers has sought to combine in this volume the class text-book and the field hand-book. This is a laudable object, inasmuch as it obviates duplication and saves expense.

Apart from the usual information, there are several distinctive features in the book. For instance, there are descriptions of the optical and microscopic properties of crushed fragments, cleavage flakes, and recrystallized products. There are also number lists of the paragenetic varieties of each mineral.

A select bibliography and a glossary add to the value of the book. The determinative section is carefully compiled. The arrangement of symbols and abbreviations is good.

# ATLIN MINING DIVISION, BRITISH COLUMBIA

The following information concerning last year's mining operations in Atlin mining division, British Columbia, has been obtained from sources believed to be dependable.

Owing to the unusual shortage of water for gravel-washing purposes, not nearly so much placer mining was done as would have under less unfavourable conditions in this respect. Notwithstanding this drawback, it is expected the quantity of gold recovered will be found to have been greater than that reported as the yield in 1911—possibly to the extent of 25 per cent. increase. This, however, will not be definitely ascertainable until the returns shall all be in.

Placer mining was done on various streams, as follows: On Pine, Spruce, McKee, Birch, Boulder, Ruby, Wright, Otter, Wilson, Lincoln, and Davenport creeks, and on O'Donnell river.

### On Pine Creek.

On Pine creek, the North Columbia Gold Mining Company, under the management of Mr. J. M. Ruffner, operated throughout the season at a disadvantage,owing to not being able to use as much water as was required, notwithstanding that it had the reservoir of Surprise lake to draw from. At no time in 1912 was it practicable to flush out the creek channel and thus get rid of the tailing, in consequence of which the recovery of gold was on the whole less than in the 1911 season, although in one of the pits the yield was better than ever before. In the season before, the company employed a varying number of men, sixty having been the maximum at any one time, and from six to fifteen monitors, mostly of large size, were used during the season; corresponding particulars for 1912 have not yet been received, but it is understood the season was an active one and results fairly satisfactory under the circumstances.

### On Spruce Creek.

Operations on Spruce creek in both 1910 and 1911 seasons gave employment to about seventy men: more than half of this number were individual miners. In 1912, however, fewer properties were worked, yet, this notwithstanding, it is thought there was in the last mentioned year an increase in the quantity of gold recovered.

### On Ruby Creek.

The Placer Gold Mines Company, with Mr. T. M. Daulton as manager, has been operating on Ruby creek several seasons. Prior to 1912 much development work was done, chiefly in hydraulicking a channel down to bed-rock, working up-stream on grade. During the time this work was in progress the production of gold was small from this creek, but last season there was a substantial increase. Toward the close of the season rich ground was worked; this was previously known to exist here, but it was never before reached by hydraulic operations. It may be expected that next season a further increase in production of gold will take place on this creek.

### On Several Other Creek.s

Lack of water caused a marked decrease on several other creeks of those mentioned earlier. It was expected that much dead-work done on Birch creek in 1911 would have led to a good showing being made in 1912, but this expectation was not realized. On Boulder creek in past years the Societe Miniere de la Colombie Britannique has done much dead-work searching for a deep-gravel paystreak, but results have not yet proved satisfactory. The Pittsburg-British Gold Company—the Hamshaw property—has been operating on McKee creek for several years, but no information is available concerning this organization's work in 1912. Wright creek in recent years has had only a few individual miners working on it. The Otter Creek Development Company's leases are on the upper part of Otter creek, and those of the Maluin Syndicate on the lower; both companies have done much development and prepared for washing a lot of gravel, but they appear to have had a disappointing season in 1912. Wilson creek has been worked by a few individual miners; the 1912 results from operations on this stream were small. On Lincoln and Davenport creeks and O'Donnell river last seasons work was entirely of a prospective nature; results were encouraging, however, and good returns in the future are looked for. The Canadian-Alaska Exploration Company, with Mr. Robert McKee as manager, has done much work on O'Donnell river, preparatory to installing either a steam shovel or a dredging plant, prospects having been adjusted good enough to warrant the provision of facilities for handling a large quantity of gravel

### New Discoveries.

A discovery of rich gravel was made on O'Donnel river, on one of the benches, but there was not sufficient prospecting done before the close of the season to determine whether its extent was considerable or only small.

Late in the season a number of locations were made on Burdette creek, a tributary of O'Donnell river. This creek is a new one on the list of those on which gold has been found. Other tributaries of that river also had attention, and locations were made on them, so that indications point to activity in placer mining on these various streams next season.

New discoveries were also reported to have been made, just before the close of the season, on creeks tributary to Teslin lake, and a number of individual claims have been located there. The gold shown as having been found on these creeks is very coarse and clean and of high quality. These discoveries are also in Atlin mining division.

### Quartz Mining Near Atlin.

Very little was done in 1912 in connection with quartz mining in Atlin division—not much more than the work requisite to keep the claims in good standing, excepting on the Engineer or Northern Partnership group and the Ben M'Chree group, both situated on Taku arm. On the former more than thirty men were employed throughout the season, prospecting and developing, and with surprising results, suggesting that the possibilities of this property are beyond the most sanguine expectations of the original holders. The latter group, which is situated at the extreme south end of Taku arm, was acquired during 1912 by some British capitalists, who have done considerable prospecting work, and made arrangements for construction of an aerial tramway, and the provision of other facilities for development and exploitation, from which important results are expected.

In Rainy Hollow country nothing was done beyond the necessary assessment work on claims not yet Crown granted. The chief reason for this was that most of the properties had been bonded early in the season to representatives of capital. Meanwhile the owners developments, but those to whom the claims had been bonded did not get so far as to commence mining work.

### Another View of the Position.

From another source the following has been received: A general review of work done on the creeks around Atlin during the 1912 season shows that there was greater activity and better results last season than for any corresponding period during several preceding years; also, that the prospects for the coming season are excellent.

Among quartz properties, the Engineer group is opening up marvellously, and there is no longer any doubt of the great value of this property. Lawson's group has also passed the probation stage, and is now regarded as being among the certainties as a paying mine. The Ben M'Chree continues to please it holders, who are preparing to next season also develop in a systematic manner the White Moose property. The work done on these properties in 1912 has shown the great mineral value stored up in this district, and has demonstrated that there may be expected many years of greater activity in mining here than the most sanguine have been looking for.

Much prospecting was done during the 1912 season, and just at its close W. Shea, an old prospector, reported having found rich gold on one of the benches of O'Donnell river. Since then other reports have been received, with the result that the benches along that river have been staked for miles, in claims and leases.

Some Indians, too, have come in and recorded discovery claims on four creeks south of Tesline lake, and have stated that they found placer gold on these at depths varying from one foot to four feet. They assert that gold can be found in all the creeks at the depth of the shovel, and they are showing faith in their discoveries by taking out miners' licenses and staking for themselves and family connections. White men have been listening intently to their stories (late in November), and already the pathfinders are on their way to the new field. Without doubt Atlin division will have a mild rush next spring, and will again rank as one of the live mining camps of the North.

---

# COLLIERY EXAMINATIONS

Abstract from the Annual Report of the Department of Public Works, Province of Alberta.

The number of candidates who presented themselves for examination during the year 1911, shows a considerable increase over the previous year, and with the steadily increasing number of mine officials qualifying each year, there should soon be no difficulty in securing a sufficient number of certified persons to fill all official positions at the mines.

The following are the questions set at the mine managers' examination held at Frank, Banff and Edmonton on September 13th, 14th and 15th, 1911:

### Mine Manager's Examination.

Paper No. 1. Time allowed, one and a half hours.

Candidates must obtain 70 per cent. of the alloted marks to pass.

### Coal Mines Act.

1. State the provisions of The Coal Mines Act as to—
   (a) Inspection of workings;
   (b) Safety lamps;
   (c) Ventilation. (15)
2. Describe briefly the duties of (a) a Mine Manager, and (b) a Pit Boss, as laid down by The Coal Mines Act. (10)
3. What are the provisions of The Coal Mines Act
4. State the rule as to the examination of a mine by the workmen, and say why, in your opinion, this rule is not more generally taken advantage of.
5. What are the provisions of The Coal Mines Act with regard to manholes? Are manholes required on a self-acting incline 90 yards long, on which workmen regarding Check-weighmen? (6)
are forbidden to travel, there being a separate travelling road? (10)
6. What accidents should be reported to the District Inspector of Mines, and to the Minister of Public Works; and what are the provisions as to the reports? (9)
7. State briefly the provisions of the Act with regard to the use and handling of explosives in mines. (14)
8. What annual returns have to be made by the owner, agent or manager? (7)
9. State briefly the provisions of the Act regarding "shafts" and "outlets." (10)
10. State the provisions of the Act with regard to the fencing of—
   (a) Places not in use;
   (b) Shafts. (11)

---

### Mine Manager's Examination.

Paper No. 2. Time allowed, two and a half hours.

Candidates must obtain 70 per cent. of the allotted marks to pass.

### Gases and Shot-Firing.

1. State what gases are given off as the result of spontaneous combustion, and discuss fully their properties. (11)
2. The quantity of air passing into a mine, measured on the intake, is 115,000 cubic feet per minute, the temperature being 65 degrees F. If the quantity measured on the return of the same air-current is 118,500 cubic feet per minute, and the temperature at this point is 72 degrees F., what per cent. of mine gases is present in the return current as it leaves the mine? (10)
3. Give your opinion as to the propagation of flame in mine explosions and discuss the different methods which are adopted for arresting the same. (9)
4. What is afterdamp, and what would be the composition of the afterdamp resulting from an explosion of firedamp containing a large quantity of air; and what would it likely be if the firedamp contained a small quantity of air? (10)
5. Explain (a) the principle features of the safety lamp, (b) the effect of the several illuminants used, and (c) state what principles control or determine the dimensions of safety lamps. (10)
6. (a) State the different kinds of explosives used in mines in the Province. (b) Give your views as to

the best kind of explosives adapted to the various conditions. (c) State your views as to the best methods of handling and caring for explosives. (d) State the methods in use for drilling holes for explosives, and what suggestions you would make, if any, for improvement in such methods. (12)

7. The air current in a certain mine is charged with marsh gas to the extent of 3 per cent., when the water gauge reading is 2.5 inches. What would be the percentage of gas in the current if it became necessary to reduce the speed of the fan till the water gauge gave a reading of only 1 inch? (10)

8. Describe the principle and practice of electric blasting. What are the dangers of shot-firing in a dry and duty mine; and what precautions would you take in performing this work? (11)

9. What do you understand by the term "diffusion of gases" and what instances do you know that appear contrary to that principle? (7)

10. Describe the safety lamp, giving an explanation why it is considered and called a safety lamp. Name the different types of safety lamps with which you are familiar. States which lamp you prefer for the use of a miner, and which for the use of a fire boss, giving reasons. (10)

### Mine Manager's Examination.

Paper No. 3. Time allowed, three and a half hours.

Candidates must obtain 70 per cent. of the allotted marks to pass.

#### Ventilation.

1. What observations and data are required to determine the quantity of air circulating in a mine, and the efficiency of the ventilating appliances? (10)

2. Name the three main qualities of a ventilating fan, and show how, having regard to the thickness of seam and the length of airways, you would determine the type and size of fan to be used. (9)

3. A current of 30,000 cubic feet of air per minute is split into two airways, A and B. Split A is 5 ft. x 8 ft. and 10,000 feet long. If split B is 5 ft. x 7 ft., what length must it be to take one-half the air, no regulators being used? (10)

4. A fan 16 ft. x 8 ft., running at a speed of 100 revolutions per minute, produces 125,000 cubic feet of air under a water gauge of 2 inches, at a certain mine; what would be the required speed of this fan and the water gauge to produce a circulation of 150,000 cubic feet of air per minute in the same mine? (11)

5. State to what extent the air current in a mine can be split keeping in view the efficient ventilation of the working places. What advantages are obtained by splitting air currents over a single continuous current in ventilating a mine? Compare the advantages and disadvantages of the different means of producing ventilation in mines with respect to their safety, effectiveness and economy. (14)

6. If 15,000 cubic feet of air per minute pass along an airway 6 ft. high by 5 ft. wide and 1,600 feet long, what will the quantity be when the length is increased to 2,500 feet, the pressure remaining the same? (8)

7. What is a water gauge, a barometer, and a hyrometer; and for what purposes are they used in connection with mining? (9)

8. The temperature in a mine being 63 degrees F. the velocity of the air current 345 feet per minute, and the size of the airway 6 ft. 6 inchs. by 8 ft. 3 ins., what weight of air is travelling per minute? (9)

9. How would you increase the volume of air in a mine without increasing the power? (6)

10. Make a neat sketch of pillar and room workings for a mine employing 145 men. Show number of workmen in each district, course of ventilation, showing air splits and crossings, stoppings, doors and regulators. Give size of return airway, also quantity of air in each split. (14)

### Mine Manage's Examination.

Paper No. 4. Time allowed, four hours.

Candidates must obtain 60 per cent. of the allotted marks to pass.

#### Practical Work.

1. Describe with sketches the different methods with which you are familiar, of extracting pillars having due regard to the greatest degree of safety to the miners and the recovery of the largest percentage of the coal. (10)

2. Describe some form of coal cutting machine with which you are familiar, and state in what seams they are to be preferred to manual labour, having regard to the thickness of coal, nature of roof and pavement. (9)

3. Describe how you would arrange your men and material for retimbering an engine haulage road without interfering with the traffic on it which occupies eight out of the twenty-four hours. It is 10 feet wide and 6 feet high within the existing timbers. The upright and crown-trees are 2 feet apart and there are to be no trees in the centre of the road. Sketch side and end views, showing how you would place the new timber in relation to the old, and if you would take out the old which is supposed to have some strength left in it. The roof is composed of 5 feet of soft shale up to a 6 feet bed of sandstone. When in your opinion is the proper time to prop such a roof for a haulage road with permanent timber, immediately on being worked or later on? (11)

4. Describe two systems of working coal with which you are acquainted, and state under what circumstances as to thickness of the seam, nature of the coal, and state of the roof and pavement, you would adopt one in preference to the other, always keeping in view the working of the coal in the easiest and cheapest manner, consistent with the safety of the men and the production of the greatest amount of lump coal. (12)

5. What chemical and geological features are there in and adjacent to a coal seam which make it susceptible to spontaneous combustion? (7)

6. Describe the general principles of a breathing apparatus for rescue work in mines and discuss the favourable and unfavourable features of such an invention. (8)

7. A hole $1\frac{1}{2}$ inches in diameter is bored into old workings containing water. The head of water is 66 feet, and length of bore hole is 25 feet. How many gallons of water will be discharged per minute at the orifice? (7)

8. What are the dangers of the presence of coal dust underground and how may they be mitigated? Describe some of the precautions that you would take to guard against accidents therefrom. (12)

9. Describe fully some method by which you would sink a large rectangular shaft through heavily watered quicksand, and state what are the limits, if any, to the use of the method which you describe. (12)

10. Suppose you are opening up a new mine in a flat seam; what would determine the kind and size of fan you would equip your mine with, and whether you would open up with a double or triple entry system,

which would you use for intake, and which for return airway? Where would you place your fan and what precautions would you take to preserve it in case of an explosion? (12)

---

### Mine Manager's Examination.

Paper No. 5. Time allowed, three and a half hours.
Candidates must obtain 60 per cent. of the allotted marks to pass.

#### Machinery.

1. Explain what is meant by each of the terms: "Heating Surface." Steam Room," "Atmospheric Pressure" and "Latent Heat." (8)

2. Enumerate the different causes of incrustation in a steam boiler. What kind of incrustation does the most harm to a boiler and in what manner may it cause an explosion? (7)

3. In a slope which is 900 feet in length and has an average pitch of 30 degrees, the quantity of water accumulating is 250,000 gallons per day. Give the size of the pumps and the required speed of the same to remove this water by pumping 8 hours per day? (10)

4. What thickness should a cast iron pipe 6 inches in diameter be made to have a bursting pressure of 4,000 pounds per square inch? (6)

5. What size of haulage engine would be required to haul an output of 100 tons per hour up an incline 1,000 yards in length, with a gradient of 1 in 6? (9)

6. A compound, triple-expansion, three-cylinder engine takes steam from boilers at 192 pounds absolute pressure, and exhausts at 3 pounds absolute; what is the total number of expansions in the steam, and what number of expansions takes place in each cylinder? Give also the cut-off and the relative areas necessary in order to equalize the work of each cylinder. (10)

7. To what use is electricity applied in the operation of coal mines? What are the advantages and disadvantages of using electricity for power or other purposes? State the conditions under which you would recommend the use of electricity for power in mines. What dangers are attendant on its use and what precautions should be taken to insure safety to those employed in the mine? (11)

8. What size of rope should be used to hoist 4,000 pounds of coal at one time? The car, cage and rope weighing 3,500 pounds. (5)

9. Describe fully—
   (a) An appliance for the prevention of overwinding in shafts;
   (b) An automatic arrangement of cut-off for winding engines. (8)

10. Describe any form of compound (2 stage) air compressor. When using a large number of drills underground, what precautions would you take and how would you arrange matters so as to make the most efficient and economical use of the compressed air at your disposal? (9)

11. Describe fully, with sketches—
   (a) How a detaching hook should be connected to the cage;
   (b) Two methods of capping a steel wire rope;
   (c) The precautions to be taken in order to see that a detaching hook is always in a safe and good working order. (10)

12. (a) What is a safe voltage to use in a mine for electric haulage? (b) If the generators are producing a 500-volt current what is necessary to be done to retain the same power but reduce the voltage to 250 volts? (10)

### Mine Manager's Examination.

Paper No. 6. Time allowed, four hours.
Candidates must obtain 60 per cent. of the allotted marks to pass.

#### Levelling.

1. Describe fully the ordinary process of levelling, stating any precautions required to ensure accuracy. (10)

2. Give a page from an imaginary level book, showing at least eight readings obtained by two settings of the instrument. (18)

3. Work out and plot the section which you have given in question 2, to any convention scale. Mark on the profile the number and elevation of each station. (16)

4. What is the average grade from the point of starting to the finish of the level, in question 2? Show grade by line drawn on profile. (11)

5. Suppose you are required to take levels along an underground roadway in order to plot a section showing both roof and floor, state what instruments you would use and how you would proceed. (11)

6. What are the benefits, present and future, of having the levels of main roads put on colliery plans? (9)

7. How would you proceed to level along an inclined road, which is 3 ft. 9 ins. high and inclined at an angle of 44 degrees? (11)

8. describe an engineer's level and say how you would determine if the instrument is in proper adjustment. (14)

---

### Mine Manager's Examination.

Paper No. 7. Time allowed, three and a half hours.
Candidates must obtain 60 per cent. of the allotted marks to pass.

#### Surveying and Mapping.

1. Explain the terms diurnal variation, dip, declination and secular variation of the magnetic needle. (9)

2. What are the requirements of The Coal Mines Act as to working plants for mines? What further information should they afford in addition to what is legally required? (11)

3. Calculate by sines and cosines the bearing and length of the closing line of the following traverse:

| Station. | Azimuth. | Distance. |
|---|---|---|
| 0 to 1...... | 31 degs. 28 mins...... | 87 feet. |
| 1 to 2...... | 351 " 35 " ...... | 138 " |
| 2 to 3...... | 276 " 15 " ...... | 168 " |
| 3 to 4...... | 149 " 25 " ...... | 103 " |
| 4 to 5...... | 69 " 15 " ...... | 63 " |
| 5 to 6...... | 221 " 15 " ...... | 137 " |
| 6 to 7...... | 111 " 13 " ...... | 91 " |
| 7 to 8...... | 49 " 40 " ...... | 53 " |

(12)

4. Plot the traverse given in question 3 on a scale of 50 ft. to 1 inch and draw the closing line from Station 0 to Station 8. (16)

5. Give a general description of the theodolite and explain the method in which you would use it in making an underground survey. (9)

6. Describe the true meridian as compared with the magnetic meridian. How does the adoption of the latter affect plans made from compass observations and added to as in mine plans from year to year? (10)

7. How would you proceed to put up sights in a room, the course of the entry being given as N. 86 deg. E. and the rooms to be turned to the left, and to make with the entry an angle of 72 degrees? (12)

8. In the case of a mine with only one shaft, which is vertical and where there is iron, which cannot be removed, in every part, explain how to connect the underground with the surface survey. (9)

9. Give sketch and dimensions of a mine car to hold 2,500 pounds of screened coal after there is 42 per cent. of screenings taken out of the car. The coal is to be loaded one foot above the car. The specific gravity of the coal is 1.25. (12)

# COAL MINES BRANCH OF THE PROVINCE OF ALBERTA

From the Annual Report (1911) of the Department of Public Works.

It will be noted from the following tables that the output for the year 1911 shows a decrease of 1,342,193 tons below the year 1910. This is due to the fact that operations were discontinued in all the large mines in the southern part of the Province owing to a strike which extended for a period of practically eight months.

| | Output Alta. & Sask. | Output Alta. |
|---|---|---|
| 1901 | 346,649 | ........ |
| 1902 | 510.674 | ........ |
| 1903 | 622,939 | ........ |

| 1910 | ...... | 3.036,757 |
| 1911 | ...... | 1,694.564 |

The above figures show that there has been a decrease of 44.19 per cent. below the 1910 output.

**Classification of Output of Coal in Alberta During the Year 1911.**

| | Tons. |
|---|---|
| Lignite coal | 964,700 |
| Bituminous coal | 649.745 |
| Anthracite coal | 80,119 |
| Coal used in coke production | 61,591 |
| Coke produced | 35.984 |
| Briquettes produced | 48,200 |

The above table shows that there has been an increase of 9.87 per cent. over the output of lignite coal for the year 1910, and decreases of 65.74 per cent. of bituminous, and 69.39 per cent. for anthracite coal below the outputs for the year 1910.

The following table indicates how the bituminous coal outputs from the different districts in the Province were disposed of:

| Tons of 2,000 lbs. | Crow's Nest Pass. | Calgary. | Lethbridge. | Edmonton. | Total. |
|---|---|---|---|---|---|
| Sold for consumption in Alberta | 309,512 | 88,609 | ...... | 10,619 | 408,740 |
| Sold for consumption in other Provinces | 64,354 | 113 | ...... | ...... | 64.467 |
| Sold for export to the United States | 36,016 | ...... | ...... | ...... | 36.016 |
| Total sales | 409.882 | 88,722 | ...... | 10.619 | 509.223 |
| Used in making coke | 61.591 | ...... | ...... | ...... | 61,591 |
| Used under colliery boilers | 41,433 | 9,377 | ...... | 3.500 | 54,310 |
| To stock | 15,213 | 174 | ...... | 9,234 | 24,621 |
| Total | 528,119 | 98,273 | ...... | 23,353 | 649,745 |

The following table indicates how the anthracite coal and briquette outputs of the Province were disposed of:

| Tons of 2,000 lbs. | Calgary District. Coal. | Briquettes. |
|---|---|---|
| Sold for consumption in Alberta | 25,677 | 23,965 |
| Sold for consumption in other Provinces | 5,705 | 23,981 |
| Sold for export to the United States | ...... | 30 |
| Total sales | 31,382 | 47,976 |
| Used under colliery boilers | 10,878 | 224 |
| Used in making briquettes | 37,859 | ...... |
| Total | 80,119 | 48,200 |

The following table indicates how the lignite coal outputs from the different districts in the Province were disposed of:

| Tons of 2,000 lbs. | Crow's Nest Pass. | Calgary. | Lethbridge. | Edmonton. | Total. |
|---|---|---|---|---|---|
| Sold for consumption in Alberta | 213 ...... | 55,196 | 181,092 | 377,745 | 614,033 |
| Sold for consumption in other Provinces | ...... | 6,937 | 166,386 | 70,038 | 243,361 |
| Sold for export to the United States | ...... | ...... | 4,578 | ...... | 4,587 |
| Total sales | ...... | 62,133 | 352,055 | 447,783 | 861,981 |
| Used under colliery boilers | ...... | 4,116 | 51,752 | 13,533 | 69,401 |
| Slack | ...... | 1,392 | 7,979 | 23,947 | 33,318 |
| Total output | ...... | 67,641 | 411,796 | 485,263 | 964,700 |

The following table indicates how the output of coke was disposed of:

| | Tons of 2,000 lbs. |
|---|---|
| Sold for consumption in Alberta | 213 |
| Sold for consumption in other Provinces | 27,669 |
| Sold for exports to the United States | 7,871 |
| Total sales | 35,753 |
| For colliery use | 463 |
| Total output | 36,216 |

The Crow's Nest Pass is the only district in the Province in which coke is produced.

The following summary shows the total sales of coal, briquettes and coke of the Province:

| Tons of 2,000 lbs. | Sold in Alta. | Sold other Provs. | Sold U.S. | Total. |
|---|---|---|---|---|
| Bituminous coal | 408,740 | 64,467 | 36,016 | 509,223 |
| Anthracite coal | 25,677 | 5,705 | ...... | 31,382 |
| Lignite coal | 614,033 | 243,361 | 4,587 | 861,981 |
| Total sales | 1,048,450 | 313,533 | 40,603 | 1,402,586 |
| Briquettes | 23,965 | 23,981 | 30 | 47,976 |
| Coke | 213 | 27,689 | 7,871 | 35,753 |

The following table shows the classification of persons employed above and below ground in cituminous fields:

| Average Number Employed. | Crow's Nest. A. | B. | Calgary. A. | B. | Edmonton. A. | B. | Total. A. | B. |
|---|---|---|---|---|---|---|---|---|
| Supervision and clerical assistance | 80 | 63 | 8 | 16 | 5 | 4 | 93 | 83 |
| Miners and helpers | .. | 829 | .. | 268 | .. | 43 | .. | 1140 |
| Mechanics or skilled labour | 170 | 47 | 22 | 10 | 14 | 2 | 206 | 59 |
| Other employees | 420 | 421 | 69 | 115 | 33 | 2 | 522 | 538 |
| Total | 670 | 1360 | 99 | 409 | 52 | 51 | 821 | 1820 |

The following summary shows the classification of persons employed above and below ground in the lignite fields:

| Average Number Employed. | Calgary. A. | B. | Lethbridge. A. | B. | Edmonton. A. | B. | Total A. | B. |
|---|---|---|---|---|---|---|---|---|
| Supervision and clerical assistance | 17 | 15 | 56 | 46 | 68 | 51 | 141 | 112 |
| Miners and helpers | .. | 112 | .. | 1287 | .. | 684 | .. | 2083 |
| Mechanics or skilled labour | 20 | 4 | 145 | 26 | 80 | 19 | 245 | 49 |
| Other employees | 26 | 5 | 360 | 161 | 288 | 78 | 674 | 244 |
| Total | 63 | 136 | 561 | 1520 | 436 | 832 | 1060 | 2488 |

The following table shows the classification of persons employed above and below ground in the bituminous, anthracite, and lignite fields:

| Average Number Employed. | Bituminous. A. | B. | Anthracite. A. | B. | Lignite. A. | B. | Total. A. | B. |
|---|---|---|---|---|---|---|---|---|
| Supervision and clerical assistance | 93 | 83 | 12 | 8 | 141 | 112 | 246 | 203 |
| Miners and helpers | .. | 1140 | .. | 150 | .. | 2083 | .. | 3373 |
| Mechanics or skilled labour | 206 | 59 | 9 | 1 | 245 | 49 | 460 | 109 |
| Other employees | 522 | 538 | 270 | 50 | 674 | 244 | 1466 | 832 |
| Total | 821 | 1820 | 291 | 209 | 1060 | 2488 | 2172 | 4517 |

| | Gross Tons. | Men. | Tons per man. | Under. | Tons per man under. |

| 1910 .. .. | 3036,757 | 5,818 | 504 | 4,090 | 742 |
| 1911 .. .. | 1,694,564 | 6,689 | 253 | 4,517 | **375 |

*During the year 1909, a strike affecting all the larger mines in the Province lasted for a period of three months.

**During the year 1911, a strike affecting all the larger mines in the Province lasted for a period of eight months.

### Summary of Statistics.

| | |
|---|---|
| Number of mines at present in operation ... | 224 |
| Number of new mines opened in 1911 ...... | 68 |
| Number of mines abandoned in 1911 ...... | 26 |
| Number of tons of coal mined in 1911 ...... | 1,694,564 |
| Number of tons of coke produced in 1911 ... | 35,984 |
| Number of tons of briquettes produced ..... | 48,200 |
| Average number of persons employed inside mines ........ | 4,517 |
| Average number of persons employed outside mines ........ | 2,172 |
| Average number of persons employed inside the mines during December, 1911 ........ | 4,734 |
| Average number of persons employed outside the mines duing December, 1911 ......... | 2,312 |
| Number of separate accidents causing loss of life ........ | 6 |
| Number of deaths caused by accidents inside the mines ........ | 7 |
| Number of deaths caused by accidents outside the mines ........ | ...... |
| Number of serious accidents inside the mines | 29 |
| Number of serious accidents outside the miles ........ | 3 |
| Number of slight accidents inside the mines. | 38 |
| Number of slight accidents outside the mines | 7 |
| Number of mine managers' certificates issued | 19 |
| Number of pit boss certificates issued ...... | 21 |
| Number of fire boss certificates issued ...... | 51 |

### Explosivs.

The following tables showing the quantity of the various kinds of explosives used during the year in mines, the estimated number of shots fired, the methods of firing them and the number of miss-fires recorded, have been compiled from returns furnished by the mine owners:

Quantity of Explosives Used in Lbs.

| Name of Explosive. | Crow's Nest Pass. | Leth-bridge. | Cal-gary. | Edmon-ton. | Total. |
|---|---|---|---|---|---|
| Black podwer ....... | | 124,647 | 38,658 | 128,026 | 291,331 |
| Monobel ...... | 109,067 | 9,794 | 22,607 | 11,890 | 153,358 |
| Samsonite ..... | 3,800 | ....... | 2,544 | ....... | 6,344 |
| Dynamite .... | 16.588 | 12.532 | 5,636 | 13,128 | 47,884 |
| Total ...... | 129,455 | 146,973 | 69,445 | 153,044 | 498,917 |

Estimated Number of Shots Fired.

| | Electric. | Fuse igniter. | Lamp. | Other fuse. | Total. |
|---|---|---|---|---|---|
| Crow's Nest Pass | 13,125 | 46,499 | 32,148 | 4,238 | 96,010 |
| Lethbridge .... | 12,456 | 9,250 | 12,000 | 98,009 | 131,715 |
| Calgary ...... | 18,850 | 10,800 | 5,000 | 29,917 | 64,567 |
| Edmonton ..... | 5.464 | 4,143 | 6,514 | 91,597 | 107,718 |
| Total ....... | 49,895 | 70,692 | 55,662 | 223,761 | 400,010 |

Number of Miss-Fire Shots Recorded.

| District. | By Electricity. | By Fuse. | Total. |
|---|---|---|---|
| Crow's Nest Pass ...... | 66 | 517 | 583 |
| Lethbridge ... ......... | 177 | 268 | 445 |
| Calgary ............ | 80 | 183 | 263 |
| Edmonton ............ | .. | 326 | 326 |
| Total ............. | 323 | 1,294 | 1,617 |

No statisties are available as to the causes of the miss-fires.

# WORK OF THE MINES BRANCH OF THE DEPARTMENT OF MINES, OTTAWA, DURING THE YEAR 1912

(Written for the Canadian Mining Journal.)

The official Summary Report reviewing the work of the Mines Branch for the calendar year 1912 is, at the present time, in course of preparation. Meanwhile, the following resume of the work undertaken during the past year may be of immediate interest.

The functions of the Mines Branch consist not only in the compilation and publication of statistical data relative to the mineral industry of Canada, but in inviting the attention of foreign, as well as local, capital to the great possibilities presented by the development of our mines, our quarries and other mineral resources. The purpose is, in a word, to aid in every possible, legitimate manner, the development of our mineral deposits.

The official programme of the work of the Mines Branch for the past year was, to a considerable extent, a continuation of work previously begun. Such a condition is but natural when the wide extent of the field to be covered is taken into consideration. Thus, for example, investigations dealing with wide spread branches of the mining industry, such as the winning of building and ornamental stones, and the development of the iron, copper and gypsum deposits of the Dominion, are all matters of very considerable magnitude. At the same time the work of the past year has also been marked by the inception of certain new investigations.

**Investigations of Iron Ore Deposits.**—The systematic investigation of the iron ore deposits of Canada carried on during the last seven years by the Mines Branch was continued during 1912 by Mr. E. Lindeman, assisted by Mr. A. H. A. Robinson, Mr. W. M. Morrison and

Mr. W. H. Davies. A detailed examination was made of the iron ore deposits in the vicinity of Sellwood, Ontario. This investigation included a study of the geological features of the iron ore deposits, the taking of representative samples of the ores, and the making of topographic and magnetometric surveys of the iron ore range. The results of this investigation will be published in bulletin form at an early date.

**Division of Chemistry.**—Mr. F. G. Wait, Chief of the Chemical Division, reports that the laboratories have been working up to their fullest capacity during the year. Considerable progress has been made in the construction and fitting of the new laboratories in the remodelled office building on Sussex Street. It is hoped that these new and much more commodious quarters will be ready for occupancy early in the coming year. The working strength of the staff of chemists has been increased by the appointment of Mr. N. L. Turner, lately of the Bureau of Mines for Ontario, who comes to the Mines Branch with experience in other fields and in the same character of work as he will be called upon to carry on here.

**Division of Mineral Resources and Statistics.**—The annual collection of statistics of the mineral production of Canada was undertaken by the Division of Mineral Resources and Statistics under the direction of Mr. John McLeish, and a preliminary report of the mineral production for 1911 was issued on March 5th, 1912. Subsequently the final report was sent to press, the following advance chapters being also issued as separate bulletins: "A General Summary of the Mineral Production of Canada during 1911;" "The Production of Copper, Lead, Nickel, Silver, Zinc and other Metals;" "Iron and Steel;" "Coal and Coke," and "Cement, Lime, Clay-Products, Stone and Other Structural Materials."

This division is now engaged in the preparation of statistics of production for the calendar year 1912, in the carrying out of which work the active co-operation of all operators is earnestly requested.

The calendar year 1911 showed a decrease in the total value of the mineral production from that of 1910, but exceeded all other previous years. Although as yet it is too early to forecast the probable production for 1912, it appears probable that this will equal, if not exceed, that for 1910. This is especially so in view of the great advance that took place in the price of metals early in the year. Probably the most important event of the year was the advent of the Porcupine Camp as an active gold producer.

During November, Mr. C. T. Cartwright spent some time in Eastern Ontario and in Quebec, gathering information in connection with the work of the Statistics Division.

**Division of Metalliferous Deposits.**—Dr. A. W. G. Wilson was occupied during nearly the whole of the first half of the year in writing and revising his report on Pyrites and Its Uses. This report is now in press and it is hoped that it will be ready for distribution about the end of January. On the completion of the Pyrites report, he resumed work on the report on the Copper Mining and Smelting Industries of Canada. The mass of material now available for this report has made it necessary to divide it into two sections which will be issued separately—one dealing with the mining end of the industry, the other with the smelting end. Towards the close of the year, Dr. Wilson spent about two months in the field for the purpose of revising the descriptive sections of these reports and bringing them up to date.

**Division of Non-Metalliferous Deposits.**—Mr. Frechette was engaged in collecting data from manufacturers throughout Canada concerning the minerals and mineral products used by them, special attention being given to the quantity, quality and source of present supply. The ultimate object of this investigation is to encourage the use of Canadian minerals by pointing out to the producers the requirements of the market and also the form in which the minerals should be prepared to best meet the needs of the various industries in which they are employed.

The work involved by the above investigation was commenced in 1911, during which year the required information was secured in the Provinces of Ontario and Quebec. During 1912 the scope of the enquiry was extended so as to include the remaining provinces of the Dominion.

Mr. Hugh S. de Schmid was, during the field season of 1912, engaged in a further investigation of the phosphate and feldspar deposits of the Dominion. The information thus acquired will be incorporated in a monograph upon these minerals which will be published by the Mines Branch in due course.

The districts visited included Parry Sound, where a mill has recently been erected for the purpose of grinding feldspar; Frontenac and Lanark Counties in Ontario, and the Lievre phosphate district in the Province of Quebec. The feldspar deposit situated in Manicouagan Bay on the lower St. Lawrence was also examined, as well as the mica-bearing permatites on Pied des Monts and Bergeronnes.

Mr. L. Heber Cole was, during the first seven months of the year, engaged in the compilation of data previously gathered in connection with his investigation of the gypsum and salt industries of Canada. Early in August Mr. Cole left Ottawa in order to complete his examination of certain deposits of gypsum in Manitoba and in Nova Scotia. The information obtained during the past two seasons will appear in the form of a revised edition of the monograph on Gypsum, issued by the Mines Branch in 1910.

**Ore Dressing and Metallurgical Division.**—During the first part of the year, the testing laboratory was operated for the experimental magnetic separation of ores received from Seven Islands Bay, Que., and from Bessemer and Childs mines in Ontario. A small sample of ore from Carter, West Virginia, which was submitted by Mr. J. W. Evans, Belleville, Ontario, was also tested in a similar manner.

Mr. George C. Mackenzie, Chief of the Division, devoted the entire field season to a detailed examination of the deposits of magnetic iron sands which occur at Natashkwan on the lower St. Lawrence. In carrying out this work, Mr. Mackenzie made use of an Empire drill and equipment. Mr. Ransom, Assistant Engineer, was, during this time, occupied in dismantling the old testing laboratory and in preparing plans for the new laboratory now nearing completion.

During the past fall the installation of machinery for the new testing laboratory was commenced. This new installation, occupying a building 75 x 50 feet, will, when completed, include the necessary equipment for experimental ore dressing either on a large or on a small scale. It will also have sufficient operative elasticity to permit of the investigation of the majority of problems encountered in dressing Canadian ores. For information concerning conditions under which such tests are undertaken, application should be made to Dr. Eugene Haanel, Director of Mines.

**Fuels and Fuel-Testing Division.**—The staff carrying on the investigations at the fuel-testing station has remained unchanged during the past year. Mr. B. F. Haanel is chief of the division; Mr. J. Blizzard, technical engineer; Mr. E. Stansfield, engineering chemist, and Mr. A. W. Mantle, mechanic.

During the earlier part of the year, the testing of peat fuel in the Korting gas producer was continued, special attention being given to the elimination of the tar fog found in the raw gas. A tar separator, designed by Mr. B. F. Haanel, was finally introduced and has given admirable results. A trial run was also conducted, using a Saskatchewan lignite in the Westinghouse, double zone, suction producer. The same producer, using peat fuel, also gave entirely satisfactory results.

During the fall, the results of certain investigations conducted by this Division appeared in the form of a report prepared by Mr. B. F. Haanel and entitled, "The Utilization of Peat Fuel for the Production of Power."

During the latter part of the year, the testing work of the Division was suspended, owing to necessary alterations to the present building and to the fact that an addition is being added to the fuel-testing plant. This addition was necessitated chiefly through the increasing requirements of the ore concentrating laboratory, but the increased accommodation will also add greatly to the efficiency of the work of the Fuel-Testing Division. Suitable accommodation is also being provided for the chemist of the Division, while a machine shop and adequate storage is also being arranged for. The space previously occupied by the ore concentrating equipment is now available for the installation of a steam boiler for testing purposes.

During the year, Mr. B. F. Haanel investigated conditions affecting power production in the west, and also presented scientific papers before the annual meeting of the American Peat Society and before the Eighth International Congress of Applied Chemistry. Mr. Haanel and Mr. Blizzard are at present in Europe, investigating peat and other power gas-producers, including both the non-recovery and the by-product recovery type.

In addition to the chemical work involved by the various tests, Mr. Stansfield, as a member of a committee of the International Congress of Applied Chemistry, has also carried out a research determination of the moisture of peat tar. He has designed and constructed an electrically heated tar still and has designed the complete equipment of the new chemical laboratories now nearing completion.

In accordance with the policy of further extending the scope of the work of the Fuel-Testing Division, Mr. J. G. S. Hudson visited the coal producing centres of the Provinces of Alberta and Saskatchewan. As a consequence, arrangements were completed whereby large and representative samples of lignites and of semi-bituminous coals are being forwarded to the fuel testing station at Ottawa. The value of these various samples, and their adaptability for use in the gas producer, will be thoroughly investigated by experimental tests conducted on a commercial basis. In addition to these commercial samples, a large number of smaller samples, representing full sections of representative seams, were collected and will be analyzed in the laboratory of the Fuel-Testing Division.

Considerable data were also gathered at the various mines visited, and included sections by measurement of the coal seams, notes relative to the character of roof and pavement, impurities of clay and shale contained in the seams, etc.

In choosing those coal mines from which samples should be taken, due consideration was given to such conditions as accessibility to markets, railroad facilities, and possible power requirements.

In addition, much information of a more general nature was gathered, including present consumption of coal for power purposes, list of existing power plants, present cost of developing power and mileage, and freight rates.

The carrying out of this work involved a personal inspection of all the larger coal mines in Saskatchewan, Alberta and British Columbia.

The possible future of peat as an asset of economic value to the Dominion, has, for several years, in the laboratory as well as in the field, been the subject of systematic investigation by the Mines Branch. The close of 1911 marked, however, the successful termination of this experimental work. Thereupon, a company, organized by Mr. J. M. Shuttleworth, of Brantford, Ont., petitioned the Government for permission to install at their own cost on the Government peat bog at Alfred a plant, in which the partial hand labour of the appliances used in our experimental plant would be replaced by machinery and power. This installation has now been completed, and, as a result, it is anticipated that the production of peat fuel on a commercial scale will be commenced in 1913.

During the field season of 1912, Mr. A. Anrep devoted his time wholly to a study of certain of the more important of the peat bogs situated in the Province of Quebec. The report on this work, which will be fully illustrated by maps and diagrams, is now being prepared for the press.

**Explosives Division.**—The Explosives Bill formulated by the Mines Branch in collaboration with the Justice Department, and which has for its object the regulation of the manufacture, importation and testing of explosives in Canada, was not reintroduced before the House of Commons during the session of 1911-12. The work of completing plans for the various building and equipment of the proposed explosives station at Ottawa was, however, continued. In furnishing detailed plans of the explosives testing station recently erected at Rotherham in Yorkshire, the Explosives Department of the Home Office of Great Britain has assisted very materially.

**Special Investigations: Building and Ornamental Stones of Canada.**—Professor W. A. Parks, of the University of Toronto, has continued his examination of the building and ornamental stones of Canada. This detailed investigation has, during the field season of 1912, been confined to the Province of Quebec. The results of this work will furnish not only descriptions of the different varieties of stone produced in the various localities, but also references to transportation facilities, and other conditions affecting production. There are, in various parts of Eastern Canada, a considerable number of quarries which were at one time large shippers, but which, owing to various causes, are at present lying idle. Professor Parks has, therefore, given special attention to a study of those circumstances which have adversely affected the stone working industry.

It is the intention of this Department to include in the present investigation all the Provinces of the Dominion, the data so gathered to constitute a monograph on the building and ornamental stones of Canada. It is, moreover, anticipated that this work will prove of special value to builders, contractors, and others, by indicating those localities in which each particular variety of stone may be most readily obtained.

Volume I. of this report has already been issued, and contains a systematic description of the building and ornamental stones occurring in that part of Ontario lying south of the Ottawa and French Rivers.

**Petroleum and Natural Gas Resources of Canada: Mr. F. G. Clapp and Mr. L. G. Huntley.**—During a part of the field season of 1912, Mr. Frederick G. Clapp, assisted by Mr. L. G. Huntley, was engaged in the preparation of a report on the petroleum and natural gas resources of the Dominion of Canada. This report will outline the history of developments, status of production, stratigraphy, drilling methods, markets, methods of transportation, quality, utilization, and such other technical details as are necessary in exploiting these resources to best advantage. Such a report is necessary for an operator in one field who may wish to be informed regarding conditions or methods existing in some other field, and it is needed, furthermore, for a layman who may intend entering the petroleum or natural gas business or associated enterprises, and who may demand truthful information regarding conditions or methods in various parts of the Dominion.

**Investigation of Metallurgical Problems of Economic Importance.**—It is generally conceded that the phase of Mines Branch operations which may be described as original research work, constitutes one of the most important features of departmental activity. Questions, concerning the application of new methods of metallurgical treatment, and the discovery of new uses for our minerals themselves, are clearly of very real importance to the mining industry of the Dominion.

A single example of the practical results that may be anticipated from such research work, is presented in connection with the conditions which at present govern the marketing of Cobalt ores. In the past the smelters have refused to pay for the cobalt and nickel content, yet it would be surprising if cobalt could not be advantageously utilized in hte production of many valuable alloys. It is obvious that other instances of a similar nature might also be cited.

Having in view, therefore, practical considerations of far-reaching importance, such as the above, the Mines Branch in 1910 took steps to further extend the scope of its technical activity. As a result, Dr. H. T. Kalmus was appointed to undertake a series of investigations on behalf of the Mines Branch, at the Research Laboratories of the School of Mining at Kingston. The following investigations may be instanced as exemplifying the character of the work that is being undertaken. An experimental investigation of the metal cobalt and its alloys; a study and report on the present status of the cobalt industry; an investigation of nickel—copper—cobalt—alloys. Such results as have been obtained up to the present time, will be referred to in the Summary Report for 1912.

**Investigation of Processes for the Reduction of Refractory Zinc Ores.**—In a previous Summary Report, the attention of the Government was called to the desirability of instituting an enquiry into modern processes for the extraction of zinc from refractory ores. At that time ample evidence, which need not be stated here, was presented, establishing the undoubted benefit that such an investigation, if successful, would bring to the zinc mining industry of Canada, particularly in the Province of British Columbia. ,

Acting on this suggestion, a sum of money was voted by the Dominion Government in 1910 to be devoted to an investigation of processes for the reduction of refractory zinc ores; for making experiments and for any other purpose that may be deemed advisable for the promotion and manufacture in Canada of zinc and zinc products from Canadian ore.

During the greater part of 1911 and 1912, work in connection with this investigation has been conducted in the metallurgical laboratory of McGill University by a staff of metallurgists under the direction of Mr. W. R. Ingalls, of New York. While this work has not as yet developed a process that will be commercially applicable to the treatment of the zinc ores of Canada, the experiments have thrown much light upon the principles of furnace design. A report fully covering the results of the work of the past year will appear in the Summary Report for 1912.

**Investigation of the Quartz Deposits of the Klondike District.**—During the field season of 1912, Mr. T. A. MacLean was retained by the Mines Branch to undertake an economic investigation of the quartz deposits of the Klondike and adjoining districts in order to obtain a reliable estimate of the probable value of these deposits Quartz veins in this part of the Yukon are plentiful, though frequently small and non-persistent, and occasionally very encouraging results have been obtained. With rare exceptions, however, it is not known, even approximately, what average amounts of gold the deposits in the different localities contain.

In order, therefore, to determine the most efficient and economical methods of treatment for the various ores, a petition was, early in 1912, presented to the Dominion Government by the Yukon Miners' Association, asking that a testing mill and a thoroughly equipped laboratory be established at Dawson. The quartz to be treated is practically all free milling.

Prior, however, to taking an action regarding the establishment of a testing mill, and also in order to obtain a fair general idea as to the gold content of the quartz, it was decided first of all to systematically sample the more important of the known occurrences, and also to endeavour to ascertain their probable lateral and vertical extent. This work was accordingly taken up by Mr. MacLean, and the results of his investigation will appear in the forthcoming Summary Report.

It should further be noted that in addition to such work as is referred to above, nearly every technical officer of the staff has been more or less occupied during the past season in gathering data which will be incorporated in the revised edition of the mining and metallurgical industry, now in course of preparation.

**Draughting Division.**—The staff of the Division is at present composed of a chief officer, two map compilers and one mechanical draughtsman.

The work assigned to this Division consists principally in the preparing of magnetometric survey and geological maps, the drawing of original plans in connection with the various mechanical plants, and the construction and drawing of original maps and diagrams used to illustrate reports.

During the past year, owing to the increase of work in this Division, the staff was increased by an additional draughtsman.

The following is a list of maps, diagrams and miscellaneous drawings prepared during the calendar year

1912. The name of the officer for whom they were prepared will be found in the margin.

| | |
|---|---|
| Magnetometric maps | 12 |
| Maps (geological and topographical) | 46 |
| Diagrams | 65 |
| Miscellaneous, photos, etc. | 145 |

**Report Covering the Operations of the Dominion of Canada Assay Office, Vancouver, B.C., During the Year Ending December 31st, 1912.**—There were during the year 527 deposits of gold bullion, requiring 597 melts and 597 assays, including the assembling and remelting of the individual deposits after purchase into bars weighing about 1,000 troy ounces each, and the assaying of same. The net value of the gold and silver contained in deposits was $975,077.14.

In the Summary Report of the Mines Branch for 1911 attention was called to certain conditions which, up to the present time, have affected in an adverse manner the amount of bullion forwarded to the Dominion of Canada assay office at Vancouver. Suggested changes recently brought to the attention of this Department should, if adopted, add very considerably to the real value of this assay office.

# PERSONAL AND GENERAL

Mr. Wm. Blakemore, of Victoria, B.C., has submitted to the Government of the province his report on the Doukhobor people resident in Kootenay and Boundary districts, to enquire into whose alleged non-observance of some of the provincial laws, and other matters, he was some time since appointed a special commissioner.

Mr. L. A. Bonner, of Barkerville, Cariboo district, B.C., was recently in Victoria prior to taking another trip to England.

An announcement made recently in British Columbia newspapers follows: "Mr. and Mrs. James McGregor, of Vancouver, announce the engagement of their second daughter, Lucy, to Mr. Charles M. Campbell, head mining engineer of the Granby mines at Phoenix. The marriage will take place January 7th." Charles McKinnon Campbell, B.Sc., B.A. (Manitoba), graduated in mining engineering at McGill in 1902. He has been with the Granby Consolidated Mining, Smelting and Power Co. more than half of the ten years that have since passed. In May, 1908, he read at a meeting of the Western Branch of the Canadian Mining Institute, held at Rossland, B.C., a very instructive paper on "Granby Mining Methods" (see C.M.I. Journal, Vol. XI, 1908), and has since done other valuable work for that branch. On Mr. O. B. Smith, jr., being appointed general superintendent of all the Granby Company's miles, Mr. Campbell was promoted to the position of superintendent of the company's mines at Phoenix. The responsibility of his position and the onerous nature of his duties will be apparent when it is mentioned that in 1912 the output of those mines was between 1,200,000 and 1,300,000 tons of ore.

Mr. W. G. Clark, foreman at the Payne mine, Slocan, B.C., who last autumn was seriously injured by an explosion in the deep-level adit, the driving of which he was superintending, is now out of the hospital. The sight of one of his eyes has been saved, but he has lost the other eye. He will probably return to Sandon, Slocan, in January.

Mr. G. B. Dean, superintendent of the Silver Ridge mine, near Three Forks, B.C., has returned to the Slocan from a visit to Spokane, Washington, U.S.A.

Mr. T. M. Daulton, manager of the Placer Gold Mines Co., operating on Ruby creek, Atlin, B.C., is spending the winter in Seattle, Washington.

Mr. W. J. Elmendorf has returned to Victoria, B.C., from Glacier creek, Portland Canal mining division, whence he went to ascertain the progress being made in driving a long deep-level adit on the property of the Portland Canal Tunnels, Ltd., of which company he is general manager.

Mr. George E. Farish, of New York, has again been giving attention to mining property in Sheep Creek camp, Nelson mining division, B.C.

Mr. W. E. Finch, manager for the Finch syndicate, which is operating under option of purchase the Idaho-Alamo group and other mines in Slocan district, British Columbia, spent the Christmas season in Spokane, Washington, with his family.

Mr. Alexander Grant, formerly manager of the Marble Bay mine, near Van Anda, Texada island, B.C., has been enjoying a visit to San Diego, California.

Mr. John Hopp, whose operations in the vicinity of Barkerville are on the largest scale of all of those who are hydraulic-mining for placer-gold in Cariboo district, B.C., is in Seattle, Washington, for the winter months, after having experienced an unusually dry and short gravel-washing season in Cariboo.

Mr. P. F. Horton is manager of the H. B. mine, situated near Salmo, Nelson mining division, British Columbia. Several hundred tons of lead ore, much of it carbonate, was shipped from this property to Trail last year. It is hoped the H. B. will be developed into a payable mine, after further development work shall have been done.

Arthur L. Ware, well known in the Kentucky and Tennessee coal fields as an engineer and machinery agent, has accepted a position with the Roberts & Schaefer Co. (engineers and contractors, Chicago), and will represent them in this territory. This company has for many years designed and built complete coal mining plants, coal washing plants, coal briquetting plants, and coaling stations. For the present Mr. Ware will make his home in Jellico, Tennessee.

Mr. John Kirkup, for years gold commissioner for Trail Creek mining division, British Columbia, has been a resident of Rossland for nearly 18 years, having commenced his official duties as mining recorder and constable at that place in March, 1895. Later he was promoted to the office of provincial government agent and gold commissioner. Having applied lately for removal to coast, the government has arranged to transfer him to Alberni, Vancouver island, where he will be local government agent.

Mr. A. G. Larson, of Vancouver, B.C., went to Colorado to spend the Christmas holidays, and arranged to visit mining districts in that State and oMntana before returning to British Columbia.

Mr. Chester F. Lee, of Seattle, Washington, a mining engineer, known to many in British Columbia, as well as the Northwestern States, is occupying part of his time in editing the Pacific Mining Journal, the publication of which monthly was commenced in Seattle last summer.

Mr. F. Chas. Merry, of Ferguson, Lardeau, B.C., for several years in charge of the Silver Cup and Nettie L. groups of mines, owned by the Ferguson Mines, Ltd., continues to superintend the development of those properties. The Silver Cup's output in 1912 was about 350 tons of ore, averaging more than 100 ozs. of silver to the ton, and between 35 and 40 per cent. lead. The ore also had an appreciable gold content.

Mr. E. C. Musgrave, who was superintendent of the Tyee gold-copper mine, at Mt. Sicker, Vancouver island, B.C., during its days of substantial profit-earning, is again in Victoria, where he will remain for about six months before returning to Mexico to look after his important interests there.

Mr. E. Rammelmeyer, of Salt Lake City, Utah, has gone to Switzerland on a six months' holiday visit. In the days of considerable activity at the Emily Edith mine, in Four-Mile camp, near Silverton, Slocan lake, B.C., Mr. Rammelmeyer was manager for the British company then owning that property.

The provincial government have let a contract for the erection of a building at Nanaimo, British Columbia, for mine-rescue training purposes. Mr. J. D. Stewart has been appointed to take charge of that station and the mine-rescue apparatus there also owned by the government.

Mr. Luther Saville, formerly of Nanaimo, is now manager of the coal mine of the British Pacific Coal Company at Slate Chuck, on Graham island, of the Queen Charlotte group, British Columbia. He is the holder of a first-class certificate of competency under the British Columbia "Coal Mines Regulation Act, 1897." Mr. Alex. Faulds, who had been in charge, has returned to Vancouver.

Dr. G. L. Tanzer, formerly managing director of a company that operated under lease the Cornell and Copper Queen gold-copper mines, at the northern end of Texada island, B.C., has returned to Seattle, in which city in earlier years he had an assay office and chemical laboratory.

Among recent applicants for enrolment as members of the Canadian Mining Institute, was Mr. B. L. Thorne, of Hosmer, Crow's Nest Pass, B.C. Thorne is one of the Hosmer officials of the Coal Mines Branch of the Canadian Pacific Railway Department of Natural Resources, of which branch Mr. Lewis Stockett is general superintendent.

Mr. John Waldbeser, for several years directed the development of the Emerald, a lead property near Salmo, Nelson mining division. Eventually the Iron Mountain, Limited, was organized, with Mr. Waldbeser as manager, and this company continues to be the only one in that part of the division regularly shipping lead ore in considerable quantity to the Consolidated Mining and Smelting Co.'s smeltery at Trail, B.C. Its output for 1912 was approximately 1,700 tons of ore, containing about 1,300,000 lbs. of lead, and 2,200 ozs. of silver. Heavy roads and consequent bad hauling adversely affected shipment of ore during the last quarter of the year.

Mr. G. B. Webster, who for some time past has been associated with mining in Slocan district, British Columbia, recently left that province on a trip to Montreal and other places in Eastern Canada.

Mr. W. C. H. Wilson, of Greenwood, B.C., office manager there for the British Columbia Copper Co., has had two very anxious months in Spokane, Washington, where his wife has been very seriously ill during that period. At last accounts there was sufficient improvement in her condition to allow of her removal from the hospital.

Mr. G. M. Colvocaresses, 43 Exchange Place, New York, has recently examined mining properties in Eastern Ontario and in the Gowganda region.

Mr. W. F. Battersby, of the Dome mine, Porcupine, was in Toronto on the 9th and 10th inst.

Mr. H. B. Pickings, formerly Deputy Inspector of Mines for the Province of Nova Scotia, has opened an office in the Metropole Building, Halifax, N.S., where he will practice as a private mining engineer. Mr. Pickings has had long and valuable experience in all the mines of Nova Scotia, particularly in the metalliferous mines.

# SPECIAL CORRESPONDENCE

## COBALT AND SUBSIDIARY SILVER CAMPS.

**The Year's Output.**—So heavily did the Nipissing and the Buffalo ship in the last month of the past year that the original estimate of 30,000,000 ounces will probably be exceeded by half a million ounces. What this is worth depends entirely on whether the Domionion or the Provincial method of estimating is adopted. The Dominion takes the total production in ounces and multiplies by the average price of silver for the year. This gives over $18,500,000. The Provincial Government allows three cents an ounce for loss in smelting and freight and treatment charges, or, in fact, what the company receives back for the product. This gives about $17,800,000. According to the method of computation, this is either a million and a half or two million dollars more for the ore this year than last, notwithstanding the fact that less was produced. If it is said that the increased price in silver represented two-thirds of the wage bill of the Cobalt camp, it will be seen what a very substantial increase this is. Moreover, it is gained without any sacrifice whatever.

The situation leaves shareholders in a very happy position. 1911 was the record year for dividends, and yet 1912 Cobalt investors will get about $1,250,000 more in dividends declared and paid than the year before.

The record of the Cobalt camp is summarized in the following table:

| | |
|---|---|
| 1904 | $ 111,887 |
| 1905 | 1,360,503 |
| 1906 | 3,667,551 |
| 1907 | 6,155,391 |
| 1907 | 9,133,378 |
| 1909 | 12,461,576 |
| 1910 | 15,478,047 |
| 1911 | 15,949,019 |
| 1912 (est.) | 17,500,000 |
| Total | $81,817,352 |

Gross value in market approximately $87,000,000.

This year's dividends will total approximately $8,-500,000, which brings the total payments for the camp, including those regularly published, English corporations and close corporations, to about $42,000,000. The dividends to January 1, 1912, were about $33,500,000.

Less and less ore is being shipped. Twenty-six mines shipped 21,763 tons, a loss of 3,947 tons in comparison with 1911. The following table shows how the tonnage shipped has fallen down since 1910, in spite of the fact that the value of the output has increased:

| Year. | Tonnage. |
|---|---|
| 1904 | 158.55 |
| 1905 | 2,336.01 |
| 1906 | 5,836.59 |
| 1907 | 14,851.34 |
| 1908 | 25,405.35 |
| 1909 | 30,057.58 |
| 1910 | 34,710.29 |
| 1911 | 25,710.22 |
| | 160,829.02 |

It is very difficult to obtain bullion figures until some time after the expiration of year, or rather it is easy to get them but hard to total them accurately. It will be seen by the table appended that the bullion shipments this year are a million ounces more than the total of the two years wherein silver bars have been shipped and the value is more than a million dollars greater.

| | | |
|---|---|---|
| Total for 1910 | 945,702.94 | $501,815.33 |
| Total for 1911 | 3,772,920.00 | 2,012,428.95 |
| Total for 1912 | 5,634,298.00 | 3,365,679.00 |
| | $10,352,920.94 | $5,879,924.28 |

Concentration first superseded the shipment of crude ore to the smelter and the Butters method of smelting the ore as first established at the Nipissing has accelerated the decline. The coming year will see very small tonnage of crude ore shipped from the camp while mechanical concentration will no more than hold its own. Syanidation and concentration and syanidation at the Nipissing, Buffalo, and Dominion Reduction Company will eventually be the standard method of handling the Cobalt ores. The riddle has been solved, as is evidenced by the fact that the Cobalt plant at Copper Cliff, which for years secured the lion's share of the high grade ore is shutting down as soon as existing contracts are finished and a clean-up can be made. The mine managers and companies now know that every cent there is to be made out of the ore they are getting; they have, in fact, eliminated the middleman, who in this instance happens to be the smelters.

There has been a most healthy and decided revival of interest in the camp. It was not found possible to inveigle the public into the game again; but syndicates of men who had a good surplus of income over expenditure have taken up nearly all the old prospects and they are being worked to-day. As the history of mining camps go, the Bailey, Casey Cobalt, Cobalt Central, Drummond, Foster, Green Meehan, King Edward, Nancy Helen, Kerry, Silver Bar, Silver Leaf, and Silver Queen, were astral shapes which no medium was capable of materializing according to the best expert opinion in the camp. Just to observe what honest and economical development has accomplished this year it is instructive to notice that the Bailey has a high grade orebody which has already yielded twenty tone of 2,000-ouce ore, and shows every evidence of persistence. The Casey Cobalt will produce a million ounces, and has a million and a half ounces blocked out on one vein alone.

The Casey Cobalt has been a consistent shipper of concentrates in the last month of the year, and has already proved a profitable investment to the syndicate that purchased it from the old company.

The Drummond is now mining 25-ounce ore at a profit and sweetening it up with various streaks of high grade before this year not known to exist.

The old Kerry lease on Cart Lake (now the Seneca Superior) has opened up a vein which for 200 feet runs 4,000 ounces to the ton and has already produced 12 cars of ore, two of which were of high grade. This is practically the result of one year's work. If development continues in the same spirit for another twelve months there should be at least fully as much progress made. This is all gain; unsuspected treasure. Very few mine managers of the old dividend earning mines attempt to make more than the most tentative estimate of ore reserves. Those doing so have in the main found satisfactory results. The Coniagas, for instance, has mined over 14,000,000 ounces, repaid all its capital to shareholders, and still has 17,441,800 ounces in sight. Mr. R. P. Rogers prefers to allow 20 per cent. for possible overestimation and calls is 13,953,000 ounces.

The most significant fact in the Coniagas' annual report is that despite the fact that the mine produced last year 3,309,724 ounces, the company was able to report that "development of new orebodies during the year has exceeded the shipments by 1,400,000 ounces." The ore reserves were compiled as follows:

Ore reserves, October 31st, 1912, are estimated as follows:

| | Ozs. |
|---|---|
| 4,480 tons high grade ore at 3,000 ozs. | 13,440,000 |
| 108,740 tons mill rock at 20 ozs. | 2,174,800 |
| 37,800 tons broken rock on stulls in mine at 40 ozs. | 1,512,000 |
| 10,500 tons mill rock in surface dumps at 30 ozs. | 315,000 |
| Total | 17,441,800 |

Of the 30,500,000 ounces to be produced by the camp Nipissing contributed 4,700,000 ounces, or within a few thousand ounces of the total of last year. How the remainder of the principal mines performed can be seen from the following table:

| Mine. | Gross production. | Dividend requirements. |
|---|---|---|
| Nipissing | $2,850,000 | $1,800,000 |
| Coniagas | *2,183,000 | 1,440,000 |
| Crown Reserve | 1,700,000 | 1,080,000 |
| McKinley-Darragh | 1,900,000 | 898,000 |
| Buffalo | *1,351,150 | 320,000 |
| Cobalt Townsite | 1,119,207 | 400,000 |
| La Rose | 1,800,000 | 749,230 |
| aO'Brien | 797,500 | ........ |
| bT. & H. B. | 561,992 | ........ |
| Cobalt Lake | 580,000 | 310,000 |
| Kerr Lake | 1,086,044 | 600,000 |
| cTrethewey | 382,800 | ........ |
| Timiskaming | 746,832 | 300,000 |
| Beaver | 464,000 | 240,000 |

*Gross production, estimated at 58c. smelter settlements.

aClose corporation.

bPays 300 per cent. about every two months.

cNo regular quarterly; paid 10 per cent. in 1912.

The eleventh day success of the Cobalt Townsite and the Casey Cobalt in the London market has created some excitement there that might be prejudicial to the sane and sober interests of the camp. It is well known that English firms actually engaged in mining are extremely well posted on the possibilities of the silver camp; but the English public can be stampeded as in the rubber boom. Anything more detrimental to the good name of the mining industry than such a stampede initiated on three-color scheme prospectuses can scarcely be imagined. There are indications that the English public are to be thrown the bait, but it is very doubtful if the fish will rise.

## PORCUPINE, SWASTIKA AND OTHER GOLD AREAS.

In spite of the industrial dispute that cut a quarter of a million dollars from the production of the camp, Porcupine made good its promise of 1911, in the past year. There are still but two mines on a producing basis, but five or six other have made such good progress in ore reserves and development that it is almost certain that they will add something to the aggregate of the coming year.

Before the end of the present year it is probable that the following companies will either have mills built and producing, mills building or mills projected. The tonnage given is the maximum expected to be obtained during the year.

Daily Milling Capacity.

| | Tons. |
|---|---|

### HOLLINGER OUTLOOK.

The Hollinger Gold Mines Company is the only producing company in Porcupine that has opened its books to the public. The results they have obtained, therefore, are of the utmost value in estimating the future of the camp. Owing to the strike and the serious condition of disorganization it has caused it is probable that a normal month's work would equal the actual amount of progress made in November and December, but conceding them at two full months it is found that the Hollinger has made a profit of $763,385 in five months.

| | |
|---|---|
| Profit for five months | $763,385 |
| Dividends paid | 270,000 |

This cannot be accounted a bad record for the first six months of actual operation.

To make the profit of $550,000 up to the end of October, "20,444 tons of ore from development, partly made up of waste rock inadvertently included from drifting and sinking, have been milled and have shown an average value of $19.70 per ton, 5,777 tons of ore from stopes have been treated and have shown an average value of $37.89 per ton. The average value of all ore removed from the mine to date is $23.69 per ton, established by treating 26,221 tons in the original test mill and in the new mill."

The mill was expected to handle 300 tons per day. Actual operations have demonstrated that with forty stamps in operation 450 to 500 tons can be milled each day. Stamp capacity has been tested up to 12 tons, and the cyanide plant up to the equivalent of 600 tons per day. An extraction was made of 97 per cent. of $30 ore.

That was the position of affairs previous to the time when 300 men walked out and left Mr. P. A. Robbins to get along as best he could. In his last report, issued with the third dividend, he says that as far as this mine is concerned, the strike is "broken." Since the strike commenced a profit of $94,013 was made up to the end of the month. There is little doubt that upwards of $100,000 profit will be made in December bringing the total for the year up to approximately $860,000.

As to the future of the property, all the premises advanced in Mr. P. A. Robbins' report of last January have been justified. He then estimated a tonnage of 462,000, with gold contents of $10,230,000. There is now more than that blocked out above the 200-foot level. A mile and a half of underground workings on eight veins had been accomplished before the strike began, and there are 41 veins on the property that carry ore of payable width and values.

### DOME PROBABILITIES.

The Dome has not seen fit to publish any figures yet. There is no secret that the mill is running well and making an extraction of 98 per cent., nor that development work has revealed extraordinary ore reserves, but as to the margin of profits in the quartz and schist they are stoping down, nothing has as yet been given out. In the mile and a quarter of development at the 60 and 100-foot level eight years' ore has been blocked out; eight years' supply, that is, if the mill were not enlarged. Between March 23 and November 1st the mill treated 65,000 tons. At the end of the year another tube mill and slime press were being installed in order to raise the capacity of the mill to 459 tons per day. This is by no means the extent of the ore reserves. Under what is known as the Golden Stairways vein the diamond drills report an orebody 365 feet wide, going to a depth of at least a thousand feet. There is little doubt that the Dome will increase the capacity of their mill very soon; and it is more probable that forty stamps will be added than merely twenty.

### McINTYRE MILL.

The little McIntyre mill commenced to treat ore on the first of March, and by the first of November 11,200 tons had been put through. The returns have enabled the company to meet current operating and development expenses. The 300-foot level of the mine revealed an excellent body of ore, but the character of the ore had so changed from that milled from the upper levels that it was decided to build another mill, including cyanide treatment. This plant is designed to treat 150 tons per day, and should have almost been finished if the strike had not delayed operations.

### PLENAURUM AND JUPITER.

The Plenaurum and Jupiter were making most satisfactory progress when the strike interfered with operations. The Jupiter was planning a mill and there is little doubt that the construction of one will commence with the spring. On the Pienaurum a long drift connects the two shafts under Pearl Lake at the 200-foot level. It has intersected some eleven veins, many of which are very promising. On one of these a winze has been sunk some 60 or 70 feet, and it has demonstrated that there is little fear that the veins at the second level will not carry as good values as at the first. Until this second level is developed there will be no thought of a mill. When the strike had hindered work for some time on this property it was decided to allow the mine to stand idle until spring; rather than to be put to the expense and trouble of fighting the strike during the winter months.

### PEARL LAKE PROPOSES A MILL.

It has just been announced that the syndicate now working the Pearl Lake mine will build a twenty-stamp mill upon the property. This decision was reached when the orebody was cut at the 400-foot level. The year will not be very old before the Rea is working again. A syndicate of moneyed men, whom Mr. John Redington represents in the North country, will erect a mill to treat the ore that is already in sight on the two upper levels and a vigorous attempt will be made to discover further lenses of good ore in the vein at the 300 and 400-foot levels. Other quartz bodies carrying good veins exposed on the surface, but as yet not developed at all, will also be opened up.

### SCHUMACHER.

It is very probable, too, that something will be made of the Schumacher. Mr. Joe Houston has now taken charge of the development of that property. It has always been regarded as one of the best prospects of the camp, and Mr. Houston's reputation is enough to guarantee a vigorous and intelligent campaign of development.

### McEANENY DEVELOPMENTS.

The McEaneny of the Crown Reserve is probably in a better position to calculate ore reserves than any property in the camp, excluding the Dome and the Hollinger. Starting the year with most discouraging prospects, there is now actually in sight three-quarters of a million dollars on one vein. A ten-stamp mill is being erected and stamps should be ready to drop in the second or third month of the year. Five stamps will be installed now; five more later on.

### DOME LAKE PROGRESSES.

The most definite advance outside the Pearl Lake area has been at the Dome Lake mine, where a high grade orebody has been blocked out for several hundred feet above the 50-foot level. A ten-stamp mill is here being erected and should be in operation about the same time as the McEaneny.

### DAVIDSON NEWS.

The fate of the Davidson is unknown; but the shareholders of the Crown Chartered do not appear to be ready to save it from the wreakage of the company. It and the Hughes-Porcupine are the only two properties that have made an progress in that portion of Whitney township and North Tisdale in which they are situated, last year. The Porcupine Lake (Hunter) have erected a plant and buildings after a careful testing of their veins with a diamond drill.

### SWASTIKA.

There will be two mills at Swastika during the coming year, one at the Swastika and the other at the Lucky Cross. At the lower levels the underground development of the Swastika has been disappointing. Very interesting from any point of view is the development of the Tough claims, near Kirkland lake. The vein, which has been developed, averaged not more than five inches on the surface; at a depth of ten feet it had widened to fourteen inches, with occasional bulges. All this ore was remarkably high grade and two shipments that have been made ran approximately $400 to the ton.

## BRITISH COLUMBIA.

The review of "Mining in British Columbia in 1912," which has already been printed in The Canadian Mining Journal, will have shown its readers that mining in the Province is, generally, in a satisfactory condition, and that the outlook is considered to be more favourable than for some years past.

The close of the year has seen activity the rule in the mining camps of the Province. The only labour difficulty at the present is that at the collieries of the Canadian Collieries (Dunsmuir), Limited, with mines at Extension and Cumberland, both districts on Vancouver Island. It is thought this trouble will be quite overcome shortly, for already the company has a fairly large number of men at work in some of its coal mines, and is making a production of coal up to about 1,000 tons a day. In Kootenay district a Board of Conciliation and Investigation is about to commence to look into the position in regard to the demand of the miners for increased pay; meanwhile, though, there is not any interruption of operations at the mines affected —some 20 in number.

### IN AINSWORTH MINING DIVISION.

Mines in Ainsworth division that shipped ore during 1912 were as follows:

**Bluebell.**—The quantity of ore mined and milled during the second half of the year (the concentrator was not operated during the first half) was approximately 33,000 tons; concentrate shipped to Trail, more than 3,400 tons; metals recovered were, silver nearly 50,000 ounces, lead about 4,172,000 pounds. Development work done proved the continuance of the big orebody below the level of Kootenay Lake. A rise made from the lower level to the surface in 1912 gave the mine a new main shaft, which was equipped with head-frame, and double-drum hoist operated by compressed air. Sinking of the old shaft is again in progress, and as soon as possible new ground will be opened therefrom and connection be made with the new shaft. Additions to plant and equipment included a new crusher house with two Blake crushers in series, and a storage bin; Sullivan compressor with a capacity of about 1,500 cubic feet free air per minute; and minor changes in the concentrating plant.

**No. 1 Mine.**—This was operated by the Consolidated Company, which, up to the end of November, had received at its smeltery at Trail from this mine 524 tons of ore averaging about 96 ounces of silver to the ton and three per cent. lead.

**Silver Hoard and Hope.**—The former of these two is situated in the old Ainsworth camp; the latter is on Princess Creek and is worked by the Florence Mining Company. Particulars of the Silver Hoard eave have already been published in the Canadian Mining Journal; some 750 feet of development work was done on the property last year, and 202.4 tons (dry weight) of ore shipped, the metal contents of the ore having been 13,846 ounces of silver and 13,711 pounds of lead. In addition several hundred tons of lower-grade ore was set aside for treatment in the future. Of the Hope, little is known to the writer; in 1911 the Florence Mining Company undertook the work of driving a tunnel to gain a depth of 500 feet. In 1912 40 tons of ore was shipped to Trail; no information of work done has been received.

**Whitewater and Vicinity.**—Shippers were: The Whitewater mine, operated by J. L. Retallack & Company, about 1,100 tons of hand-picked ore, averaging about 75 ounces of silver to the ton and 35 per cent. lead; the Utica, stated to have shipped $50,000 worth of ore; and the Panama, from which 61 tons of high-grade ore was sent to Trail.

## NELSON MINING DIVISION.

Work is being continued at the Granite-Poorman gold mines, the Queen Victoria and Eureka copper mines, and the Molly Gibson and La France silver-lead mines, all situated in the northern part of this division. Of these, the Granite-Poorman group is having its ore milled, shipping to the Trail smeltery only the concentrate produced after the pulp has passed the amalgamating plates; the Queen Victoria shipped to the British Columbia Copper Company's works at Greenwood by the end of December about 1,000 tons of low-grade copper ore, that having been the output from the time production was commenced late in November, after this mine had been purchased by that company and work resumed at it; the Molly Gibson's output for the year was between 2,000 and 3,000 tons, much of it concentrate.

Concerning the Dundee, in Ymir camp—development work has been in almost continuous progress on this property for the past three years. The most important work done was that of driving a tunnel, starting from a point at the southwestern corner of the property, where recommended some years ago by Mr. Bernard MacDonald in his report, made after he had examined the Dundee. The main adit has been driven 1,851 feet, and there has been some later drifting to the extent of about 600 feet. In addition some 400 feet of diamond drilling has been done. By far the greater part of this work was cross-cutting in country rock, only the last 200 feet having been driving on the vein. In the course of the cross-cutting several showings of ore have been met with; these will be opened later. The present object is to continue the main drift until it shall be under the old shaft, which will involve driving nearly 500 feet farther. The drift is being advanced about 5 feet a day; when it shall be under the old shaft, raising will be undertaken and continued until connection shall be made with the old workings, which are down to a depth of 260 feet from the surface, and approximately 640 feet above the level of the long tunnel above-mentioned. This means that when the connection shall have been made, the mine will be opened to a depth of 900 feet from the surface.

No continuous bodies of ore have yet been found at the greater depth worked, but the vein is there, well defined and running on a similar course to that shown in the old shaft workings. The diamond-drill shows it to be about 40 feet in width between walls. Some bunches and small streaks of ore were lately encountered, and it is expected that an ore shoot of considerable size will soon be entered. The drift has latterly been chiefly in quartz, heavily mineralized with iron pyrites and having small quantities of galena and zinc and some intrusive rock. A water-driven compressor supplies air for operating the machine drills used in drifting. No other work is planned for the time being—just to continue development along similar lines to those now being followed.

Other mines in Ymir camp are being worked, and still others about Salmo and Erie, and in Sheep Creek camp, of which some information will be given in the early future. Of these, the Yankee Girl, near Ymir, the Emerald, near Salmo, the Second Relief and Arlington, at Erie and the Queen and Motherlode in Sheep Creek camp, are the chief producing mines in the southern part of Nelson division.

## ROSSLAND AND TRAIL.

While exact figures of production of Rossland mines are not yet available, it is known that the quantity of ore produced in 1912 in Trail Creek division, which includes Rossland camp, is approximately 240,000 tons, as compared with 254,000 tons in 1911. Information received to date makes it appear that the Centre Star group shipped 31,000 tons less ore in 1912, and that Le Roi No 2 Company's mines also show a decrease in quantity; on the other hand, Le Roi made a gain of about 25,000 tons. There must be some good reason for the decreases in output mentioned, since it is well known the Centre Star group has much ore in sight, for it was reported to shareholders in the Consolidated Mining and Smelting Company at the last annual meeting, held in October, that "our Rossland mines show an increase in the amount of ore developed, with, we believe, a higher average value." Le Roi No. 2 reported, for its fiscal year to September 30th last: "Beside the discoveries of numerous oreshoots in the better-known veins in the upper ground, the most important development is that of an orebody on the 1650 (Le Roi) level. This is the deepest ore known in our ground and is of good metal content, size and character, and augurs well for the future of this part of the property in depth. Development is in progress here."

The smaller shippers in Rossland camp did not as a whole come up to expectations in the matter of output, since together they made a decrease in quantity. However, the outlook for some of them—the Blue Bird and Phoenix particularly—is decidedly promising, in both cases much better than at the close of 1911.

The Inland Empire, situated in an outlying part of the division, in the mountains westward from Rossland camp, completed the installation of its 10-stamp mill and commenced crushing ore late in the year. While production was small, it is an advance to have got to the producing stage, especially as it is expected an output will be regularly maintained. The mine has been developed to a depth of 300 feet, and levels have been opened at 70, 140, 200 and 300 feet respectively. The ore is of such a character that the saving of gold on the amalgamating plates is light, most of the value being recovered in concentrate, which is smelted at Trail.

# STATISTICS AND RETURNS

## COBALT ORE SHIPMENTS

The ore shipments for the week and year to date are as follows in tons:

| | Week Dec. 27 | Year to date |
|---|---|---|
| Bailey | 20.00 | 41.57 |
| Beaver | ...... | 163.75 |
| Casey Cobalt | ...... | 255.15 |
| City of Cobalt | ...... | 914.99 |
| Buffalo | 59.70 | 1,163.54 |
| Cobalt Lake | 30.10 | 1,056.51 |
| Cobalt Townsite | 67.76 | 1,867.78 |
| Chambers-Ferland | ...... | 500.93 |
| Coniagas | ...... | 1,997.90 |
| Crown Reserve | 19.99 | 457.83 |
| Drummond | 30.07 | 449.84 |
| Hudson Bay | ...... | 662.85 |
| Kerr Lake | ...... | 743.05 |
| La Rose | 106.26 | 3,538.93 |
| Lost and Found | ...... | 27.80 |
| McKinley-Darraugh | ...... | 2,509.16 |
| Nipissing | 27.86 | 1,803.62 |
| Penn. Canadian | ...... | 97.90 |
| O'Brien | ...... | 411.43 |
| Provincial | ...... | 22.22 |
| Right of Way | ...... | 242.82 |
| Temiskaming | ...... | 958.66 |
| Trethewey | 27.01 | 577.05 |
| Wettlaufer | 50.00 | 487.21 |
| Colonial | 13.33 | 76.47 |
| Dom. Red. Co. | ...... | 119.41 |
| Peterson Lake Seneca Superior). | 41.16 | 391.75 |
| Hargraves | ...... | 47.35 |
| Silver Queen | ...... | 31.25 |
| Totals | 534.24 | 32,171.24 |

The bullion shipments of the week were the following:

| | Ounces. | Value. |
|---|---|---|
| Nipissing | 54,464.00 | $36,756.00 |
| O'Brien | 15,736.00 | 9,722.00 |
| Buffalo | 10,550.00 | 6,600.00 |
| Miller Lake-O'Brien | 946.00 | 788.00 |
| | 85,696.00 | $58,866.00 |

## B. C. ORE SHIPMENTS

Exceeding the previous week ending December 28th, 1912, production by over 4,00 0tons, the production of the mines in the Boundary district last week was 44,931 tons and brought the total for the year over the 2,000,000 ton mark for the first time in the history of the district.

**Consolidated Company's Receipts.**

# PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assaye. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

## PUBLICATIONS

**The Geological Survey has published maps and reports dealing with a large part of Canada, with many local areas and special subjects.**

A catalogue of publications will be sent free to any applicant. A single copy of a map or report that is specially desired will be sent to a Canadian applicant free of cost and to others at a nominal price. The applicant should state definitely the Precise area concerning which information is desired, and it is often of assistance in filling an order for a map or report if he states the use for which it is required.

Most of the older reports are out of print, but they may usually be found in public libraries, libraries of the Canadian Mining Institute, etc.

### REPORTS RECENTLY ISSUED:

**CANADA**

1085. Descriptive Sketch of the Geology and Economic Minerals of Canada. Accompanied by a geological and mineral map of Canada, by G. A. Young and R. W. Brock.
1218. Summary Report of the Geological Survey for 1911.

**NEW BRUNSWICK and NOVA SCOTIA**

1113. Memoir No. 16. The Clay and Shale Deposits of Nova Scotia and portions of New Brunswick, by H. Ries and J. Keele.

**QUEBEC**

1110. Memoir No. 4. Geological reconnaissance along the line of the National Transcontinental Railway in Western Quebec, by W. J. Wilson, accompanied by a map.

**ONTARIO**

1213. Memoir No. 28. The Geology of Steeprock Lake, Ontario, by Andrew C. Lawson. Notes on Fossils from Limestone of Steeprock Lake, Ontario, by Charles D. Walcott.

**NORTH WEST PROVINCES**

1204. Memoir No. 24. Preliminary Report on the Clay and Shale Deposits of the Western Provinces, by Heinrich Ries and Joseph Keele.
1211. Memoir No. 27. Report of the Commission appointed to investigate Turtle Mountain, Frank, Alberta, 1911.

**BRITISH COLUMBIA**

940. Report on Graham Island, B.C., by R. W. Ells. (Reprint.)
1121. Memoir No. 13. Southern Vancouver Island, by Charles H. Clapp.
1175. Memoir No. 21. The Geology and Ore Deposits of Phoenix, Boundary District, B.C., by O. E. LeRoy.

**YUKON and NORTH WEST TERRITORIES**

1080. Report on a part of the North West Territories drained by the Winisk and Attawapiskat Rivers, by Wm. McInnes.

### MAPS RECENTLY ISSUED:

**CANADA**

1042. Mineral Map of Canada. Scale 100 miles to 1 inch.

**NOVA SCOTIA**

1133. Map 13A. Kingsport sheet, Nova Scotia, No. 84. Scale 1 mile to 1 inch.

**NEW BRUNSWICK**

**QUEBEC**

1112. Map 12A. Vicinity of the Tranco ntinental Railway, Abitibi District, Quebec. Scale 4 miles to 1 inch.
1178. Map 32A. Larder Lake and Opasatika Lake, Nipissing, Abitibi and Pontiac, Ontario and Quebec. Geological. Scale 2 miles to 1 inch.

**ONTARIO**

964. Geological map of portions of the districts of Algoma and Thunder Bay, Ontario. Scale 8 miles to 1 inch. Second edition.

**ALBERTA**

1132. Map No. 7A. Bighorn Coal Area, Alberta, by G. Malloch. Scale 2 miles to 1 inch.

**BRITISH COLUMBIA**

792. West Kootenay sheet, B.C. Geological. Scale 4 miles to 1 inch.
1167. Map 29A. Mother Lode and Sunset Mines, Deadwood, B.C., Topographical. Scale 400 feet to 1 inch.
1147. Map 19A. Lardeau, West Kootenay, B.C. Topographical scale 4 miles to 1 inch. Contour interval 500 feet.
1197. Map 47A. Law's Mining Camp near Tulameen, B.C. Geological. Scale 600 feet to 1 inch. Contour interval 50 feet.
1219. Map 54A, Nanaimo Coal Area, Vancouver Island, B.C. Scale $1\frac{1}{2}$ miles to 1 inch. Contour interval 100 feet.

**YUKON and NORTH WEST TERRITORIES**

1089. Map 9A. Explored Routes on Parts of the Albany, Severn and Winisk Rivers. Scale 8 miles to 1 inch.

NOTE.—Maps published within the last two years may be had, printed on linen, for field use. A charge of 10 cents is made for maps on linen.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon. Letters and samples that are of a Departmental nature, addressed to the Director, may be mailed O.H.M.S. free of postage.

*Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.*

# BUYERS AND SELLERS OF METALS

# PROVINCE OF QUEBEC

**Department of Colonization, Mines, and Fisheries**

***The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, Etc.***

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

**MINERS' CERTIFICATES.** First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is $10.00, and it is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

**WORKING CONDITIONS.** During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

**SIX MONTHS AFTER STAKING.** At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

**MINING LICENSE.** The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days labour on each forty acres.

**MINING CONCESSION.** Notwithstanding the above, a mining concession may be acquired at any time at the rate of $10 an acre for SUPERIOR METALS when more than 20 miles distant from a railway and $20 an acre when less than 20 miles.

For INFERIOR METALS the prices are $2.00 and $4.00 an acre respectively.

The attention of prospectors is specially called to the territory in the North-Western part of the Province of Quebec, north of the height of land, where important mineralized belts are known to exist.

**PROVINCIAL LABORATORY.** Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, MONTREAL, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The Bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

**THE HONORABLE THE MINISTER OF COLONIZATION, MINES, AND FISHERIES, QUEBEC.**

# The Minerals of Nova Scotia

The extensive area of mineral lands in Nova Scotia offers strong inducement for investment.

The principal minerals are:—Coal, iron, copper, gold, lead, silver, manganese, gypsum, barytes, tungsten, antimony, graphite, arsenic, mineral pigments, diatomaceous earth.

Enormous beds of gypsum of a very pure quality and frequently 100 feet in thickness are situated at the water's edge.

The Province contains numerous districts in which occur various varieties of iron ore practically at tide water and in touch with vast bodies of fluxes.

The Gold Fields of the Province cover an area of approximately 3,500 square miles. The gold is free milling and is from 870 to 970 fine.

Deposits of particularly high grade manganese ore occur at a number of different localities.

Tungsten-bearing ores of good quality have lately been discovered at several places and one mine has recently been opened up.

High-grade cement-making materials have been discovered in favorable situations for shipping.

Fuel is abundant, owing to the presence of 960 square miles of bituminous coal and 7,000,000 acres of woodland.

The available streams of Nova Scotia can supply at least 500,000 H. P., for industrial purposes.

Prospecting and Mining Rights are granted direct from the Crown on very favorable terms.

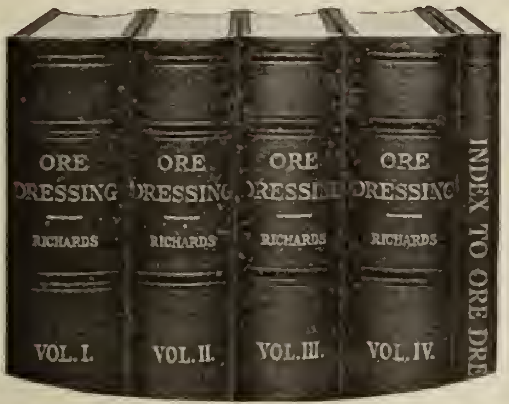
## ALPHABETICAL INDEX TO ADVERTISERS

# New and Standard Mining Books



## Ore Dressing

By Robert H. Richards, S.B., LL.D.,

Professor of Mining and Metallurgy, Massachusetts Institute of Technology.

Four Volumes, 2,000 pages, 6x9, illustrated. Per set, $20.00 (£4, 4s) per volume, $5.00 (2/2.)

An Encyclopedia on the Dressing of Minerals. Volumes I and II, published in 1903, covered the practice of the world to that date with the underlying principles and unchanging data. Volumes III and IV supplement, but do not supplant the earlier work. The fresh material—tube mills, Wilfley tables, magnetic separation, flotation processes, etc.—required two new volumes.

Plant equipment, comparative efficiency, costs of operation, speed, capacity, water power, life of Machines, etc., are covered in great detail. Index to all four volumes bound separately, supplied free with complete sets or Volumes II. and IV. when sold together.

Vols. I. and II.

CONTENTS.—Chapter I.—General Principles. Part One—Breaking, Crushing and Comminuting. Chapter II.—Preliminary Crushing. III.—Rolls. IV.—Steam, Pneumatic and Spring Stamps. V.—Gravity Stamps. VI.—Pulverizers Other Than Gravity Stamps. VII.—Laws of Crushing. Part Two—Separating. Concentrating or Washing. Chapter VIII.—Preliminary Washers. IX.—Sizing Screens X.—Principles of Screen Sizing. XI.—Classifiers. XII.—Laws of Classifying by free settling in water. XIII.—Hand Picking. XIV.—Jigs. XV.—Laws of Jigging. XVI.—Fine Sand and Slime Concentrators. XVII.—Amalgamation. XVIII.—Miscellaneous Processes of Separation. Part Three—Chapter XIX.—Accessory Apparatus. Part Four—Mill Processes and Management. Chapter XX.—Summary of Principles and Outlines of Mills. XXI.—General Ideas on Milling. Appendix.

Vols. III. and IV.

Chapter XXII.—General Principles. XXIII.—Preliminary Crushing. XXIV.—Rolls. XXV.—Steam, Pneumatic and Spring Stamps. XXVI.—Gravity Stamps. XXVII.—Pulverizers Other Than Gravity Stamps. XXVIII.—Laws of Crushing. XXIX.—Preliminary Washers. XXX.—Sizing Screens. XXXI.—Principles of Screen Sizing. XXXII.—Classifiers. XXXIII.—Laws of Classifying by Settling in Water. XXXIV.—Hand Picking. XXXV.—Jigs. XXXVI.—Laws of Jiggling. XXXVII.—Fine Sand and Slime Concentrators. XXXVIII.—Amalgamation. XXXIX.—Miscellaneous. Processes of Separation. XL.—Accessory Apparatus. XLI.—Summary of Principles and Outlines of Mills. XLII.—General Ideas on Milling. Appendix. Index.

*Issued January 6, 1912.*

## Stamp Milling

By Algernon Del Mar, Mem. A.I.M.E., etc.

134 *pages*, 98 *illustrations*, $2.00 (8/6).

A new treatise by a writer with a broad, practical experience.

Algernon Del Mar has been connected with the construction and operation of mills of all sizes in both the United States and foreign countries. He describes South African as well as "Western" practice.

He gives complete modern data, supplemented by a series of excellent illustrations.

CONTENTS: Evolution of the Gravity Stamp Mill. General Principles of the Stamp Mill. Practical Working of the Stamp Mill. Limitations of the Single Unit and Five-stamp Unit Batteries. History of Amalgamation. Amalgamation. Stamp Mill Construction.

*Second Edition; Total Issue,* 6,000.

### Metallurgy of Iron and Steel

By Bradley Stoughton, B.S., Ph.B.

Consulting Engineer.

537 *pages*, 370 *illustrations*, $3.00 (12/6).

A new edition, completely revised and enlarged—of the standard work. It covers the latest developments.

Among the important changes where entirely new matter is presented are those on the manufacture of pig iron; fuels; Bessemer, open-hearth processes, special open-hearth and duplex processes; malleable cast iron; heat treatment; electro-metallurgy.

### Mining without Timber

By R. B. Brinsmade.

309 pp., illustrated.

$3.00 (12/6).

A timely and valuable book. Gives the best American practice, from leading mining centres.

Among the methods described are: Surface Shovelling in Open Cuts; Surface Mining; Underhand and Overhand Stoping with Variations; Back Caving; Block Caving; Slicing; Advancing Long Wall for Seams; Pillar Systems for Seams; Flushing System for Seams.

*Second Edition.*

### Manual of Fire Assaying

By Charles H. Fulton, E.M., D.Sc.

Prof. of Metallurgy, Case School.

219 *pages, illustrated,* $2.00 (8/6).

A new edition—thoroughly revised, reset and enlarged.

It covers all the recent progress and is up to date throughout.

Especially valuable is the new material on assay furnaces, assay fluxes, cupellation, and special methods of assay.

### Design of Walls, Bins and Grain Elevators

By Milo S. Ketchum,

University of Colorado.

*Second Edition; Fully Revised.*

556 *pp., illustrated,*

$4.00 (17s.).

The best modern book on design and construction of walls, bins, etc.

The new edition is enlarged by 150 pages and is a thorough revision. It is up to date again.

## Metallurgy—*Vol. 1—Fundamentals*

By Herbert Lang, Author of "Matte Smelting."

255 *pages*, 6 *x* 9, *illustrated*, $3.00 (12/6).

A new work with a fresh viewpoint. Volume one is a unit in itself. It makes the systematic approach to the subject, direct and easy. It discusses fundamentals in a scientific, logical manner.

# Amatite ROOFING

## Best for Mine Buildings

AMATITE is made so as *not to need painting*. It has a real mineral surface which is better than paint. It consists of mineral particles gripped in a firm, tough matrix of pitch—*the greatest waterproofing material known.*

The mineral matter and the pitch form, in fact, a sort of plastic concrete which is thoroughly weatherproof and needs no painting.

Amatite is worth much more to you than any roofing which requires painting every two years. You could well afford to pay a higher price for it. Nevertheless Amatite actually costs *less* than painted roofings of even less weight and will last longer.

The value of a "no paint" roofing, as contrasted with the various painted kinds, is so obvious that Amatite has attained great popularity.

Sample and illustrated booklet free on request.

## INTERNATIONAL GEOLOGICAL CONGRESS

Most impressive are the preparations being made for the Canadian meeting of the International Geological Congress. A large amount of money has already been carefully and judiciously expended, and much more will have to be disbursed before the delegates reach Canada. Private citizens are giving their time, energy and money for the cause. Strong and representative committees have been organized. The Provinces of Nova Scotia, Quebec, Ontario, and British Columbia have contributed handsomely to the general fund. So, also, has the Dominion Government. And it is not to be believed that New Brunswick, Alberta, Manitoba, and Saskatchewan will allow this rare opportunity to pass without giving tangible evidence of their appreciation of its importance.

Let us for a moment glance over the history of the Congress, first, however, touching upon its character and objects. To quote from a pamphlet recently written by Mr. H. Mortimer-Lamb, "the objects of the Congress may be briefly summarized in the general statement that by means of the periodical meetings the results of knowledge acquired in any one country are given a universal application and significance. The Congress endeavours to provide, for example, for the adopting of uniform systems of mapping, nomenclature, and classification of rocks, fossils and minerals; and in other directions broadens the boundaries and extends the usefulness of geological science." Such tremendous undertakings as the completion of a geological map of Europe have been successfully carried through, and it is possible that a geological map of the world may be forthcoming within a few years. These, however, while they are the most striking, are not the most beneficent results that flow from the Congress. The intercourse of trained thinkers, the contact with new types, the personal comparison of notes, and the unexampled facilities for seeing extensive tracts of country that most of the delegates have not seen before, are profitable alike to the members of the Congress and to the country visited.

The membership of the Congress comprises professional geologists and persons engaged in other allied professions. There is, however, no hard and fast line drawn, although the official delegates are always representatives of corporate bodies. Nevertheless, many foreign visitors will, no doubt, come in their private capacities.

The first meeting of the Congress was held in France in 1878. Including this gathering there have been altogether eleven Congresses held at intervals of three years. The principal countries of Europe, the United States, and Mexico have been the scenes of action. For the first time Canada is now to be honoured.

The regular attendance has ranged between 140 and 703, and as many as thirty-six countries have been represented. It is estimated that the foreign contingent at the coming Congress will number at least 700, and may exceed this figure considerably. Of course, every local meeting, and every excursion will be attended by many Canadians. Thus it is possible that on such excursions as that to Cobalt and Porcupine the total attendance may run up to almost twice the first estimate.

The transportation companies have been so generous in their attitude towards the Congress, that no insuperable difficulty is expected in handling the excursions.

Fuller particulars of the coming International Geological Congress will be found on another page. The article is a transcript of a speech delivered by Mr. G. G. S. Lindsey before the Toronto Branch of the Canadian Mining Institute.

## NEWSPAPER JOURNALESE.

The following is from a Toronto newspaper:

> "They have dug up a Sourauphulous in Southern Alberta. As the intelligent animal had been buried several thousand years there was every excuse for its having gone sour in the meantime."

As the intelligent humourist of the newspaper in question has taken on himself the duty of revising paleontological orthography, and as he has not the excuse of having been buried "several thousand years," and as his joke is based upon a profound and complete misconception, and as it is quite as archaic as the innocent mispelled monster, we therefore find him guilty of something far removed from humour.

## MINE RESCUE WORK IN CANADA

The Commission of Conservation deserves commendation for its latest publication. For some time the subject has been before the public. The Commission has built up a strong system of publicity ,and it is well that the vital topic of mine rescue work should be given the benefit.

The pamphlet, "Mine Rescue Work in Canada," has been compiled by Mr. W. J. Dick, the mining engineer of the Commission. It covers, very briefly, a comparison of death rates in Canadian and foreign collieries, a description of apparatus, legal requirements abroad, Canadian establishments, and the general work of organization.

Although in other countries coal mine operators are compelled by law to instal rescue apparatus, in Canada, where authority for such legislation is vested in the Provincial Governments, the Province of British Columbia alone enforces their use. Nevertheless, owing entirely to private enterprise, Nova Scotian mine owners were first in this humane movement.

In addition to the four small stations equipped by the British Columbia Government, there are four privately-owned stations. Moreover, several companies are supplied with apparatus. In Alberta there are two, with a third under construction; and in Nova Scotia there are three exceedingly well equipped stations. Particulars of all these will be found elsewhere in this issue.

Whilst Canadian operators are following the lead of European mines, it is not out of order here to claim some credit for the Canadian Mining Journal. We were the first publication in Canada to advocate in any way the adoption of rescue apparatus and the subject has been repeatedly and emphatically referred to in these columns.

## UNITED STATES GEOLOGICAL SURVEY

The thirty-third annual report of the United States Geological Survey has just been issued. In reviewing therein the work of the department during the past year the director, Mr. George Otis Smith, takes occasion to emphasize a point that is not properly appreciated even by mining men, certainly not by the general public, namely, that scientific investigations are inseparable from economic work. "In any field," he remarks, "economic work of the highest rank is impossible without full knowledge of the scientific laws and principles pertaining to the subject of the work; but as there is no application of geology that does not involve unsolved problems, some of them of the highest importance, the best knowledge available is nevertheless relative. It thus follows that the broad and searching observations which should accompany every piece of good economic work comprehend data that are eventually combined in the construction of new scientific hypotheses, some of which, as more observations accumulate, grow into established laws or principles that are in turn of the greatest practical consequence. Thus the detailed studies of the metalliferous deposits in one region or another bring to light evidence from which to determine the genesis of the ores and the modes or conditions of their occurrence, and the economic inquiry becomes more intelligent and successful when once this new principle regarding the mode of an ore occurrence is understood." Mr. Smith gives as an interesting illustration of the deduction of a principle from data gradually accumulated from investigations in several fields, the conclusions presented in the paper by Mr. W. H. Emmons on the enrichment of sulphide ores; while an illustration of scientific results based on a long period of field studies, is found in the pre-Paleozoic history of Central North America, as described in the monograph by Van Hise and Leith on the geology of the Lake Superior region.

As indicating the broad-minded policy by which the affairs of the United States Geological Survey are governed, it may be noted that many of the scientific results of the survey's operations are frequently first published either in technical periodicals or in the transactions of scientific societies. The director explains in his annual report that this practice presents an opportunity for the free discussion of scientific theories and problems that otherwise would not be feasible.

## MARITIME PROVINCE IRON ORES

In our last issue we noticed editorially the excellent work that was done last year by the Nova Scotia Steel & Coal Company in its Wabana mines, Bell Island. Newfoundland. The Wabana ore. as our readers are doubtless aware, is shipped to the Scotia blast furnaces at North Sydney.

Encouraging as is the progress made by the above-mentioned company, it is even more encouraging to learn that the local iron mines of New Brunswick and Nova Scotia are to produce more ore during 1913 than ever before.

For various sufficient reasons, the Torbrook and Nictaux mines (Nova Scotia) belonging to the Canada Iron Corporation produced only 30,000 tons of washed ore. As a matter of fact, the washing plant was in commission for only two months. Its capacity is about 18,000 tons per month. It will run steadily throughout the current year. Already orders for 100,000 tons of washed ore have been booked, and there seems to be a ready market for the product, not only in Europe but in the United States.

The mines are being equipped for an output of 1,000 tons per day.*

Near Bathurst. New Brunswick, where are situated the other Maritime properties of the corporation, a similar washing plant has been erected. After the completion of the plant, 90,000 tons of washed ore were shipped, late in 1912, to United States ports. Orders for 1913 have been booked to the extent of 200,000 tons. Additional equipment will bring the plant's capacity up to 1,500 tons per day. Stripping by means of steam shovel will much facilitate this year's quarrying. Tide water docks at Newcastle are distant about seventeen miles.

The bold, though sound, development policy of the Canada Iron Corporation will enable it to place upon the market about 300,000 tons of high-grade non-phosphatic magnetite and, roughly, 200,000 tons of excellent phosphatic hematite and grey calciferous magnetite. This, of course, implies that the mines will live up to expectations. That they will do so appears assured.

This being the case, Nova Scotia and New Brunswick will immediately leap into the forefront of Canadian iron-ore producing provinces. But more than this will follow. No enterprises of this kind are successful without bringing in their train other new concerns, together with a general increase of the country's prosperity.

*(See special N. S. issue, Sept. 15, 1912, p. 637 et seq.)

## MINING AND RAILWAYS

Some very illuminating facts are contained in a recent Government blue book, the Annual Report of the Department of Railways and Canals for the fiscal year ending March 31, 1912. In a tabulated statement of the principal freight carried over the Intercolonial Railway, it is observable that the direct products of the mine supply almost 33 per cent. of all the freight handled. The commodities falling into this category are as follows: Coal and coke, ore, sand, stone, salt, slate and granite, and phosphate. Petroleum, all iron products, brick, lime, and cement come under the head of manufacturers. It is a notable fact that, even with this arbitrary classification, the products of mines furnish more than any other class of freight. Manufactures yielded about 31 per cent. of the total, as against the 33 per cent. mentioned above. Products of the forest, products of agriculture, and products of animals followed in the order indicated.

Tapping a region of immense mining possibilities, there is not the least room for doubting that the Intercolonial will depend more and more largely upon the products of the mine for any rapid growth in its freight traffic. The whole situation is worthy of study.

If this argument should be supposed to require further explication, it is only necessary to add that some of the largest items under the head of manufactures are the semi-finished or finished products of smelting and metallurgical establishments.

A thorough investigation of the situation would assuredly repay any reasonable expenditure.

## INTERMITTENT CYANIDATION

A short article published on another page deals with this timely subject. It is claimed by the author that intermittent cyanidation has not had fair consideration at the hands of metallurgists. It is pointed out that, theoretically at least, the advantages are in favour of intermittent as compared with continuous cyanidation. Continuous treatment is not ideal. The finer pulp is treated too long, the coarser, since its transit is too rapid, is not treated long enough.

These conditions are corrected by the simpler system of intermitten decantation, which provides proper agitation as a part of the process.

We hope that some of our readers will send in their opinions on this matter.

## EDITORIAL NOTES

The King Edward mine at Cobalt, as mentioned by our Northern Ontario correspondent, is showing symptoms of good ore. The King Edward is now being worked on a scale commensurate with probabilities. Formerly it was operated on florid hopes. The change is one of the benefits of the rational leasing system.

---

"Dios Nos Guie" is the motto over the entry to a well-known Mexican mine. Being translated, it signifies "God Guide Us." Whilst there is a touch of pathos in this prayerful legend, it is most eminently opposite. Appropriate to many a mine would be the rendering "God Help Us."

---

Canada now ranks seventh amongst the copper producing nations of the world. Last year its estimated production was 33,000 long tons. This slightly exceeded Germany's production, and was slightly less than that of Chili.

---

It is announced that the Indian Geological Survey has discovered the accurrence of asbestos of excellent quality in Idar State. The mineral is said to be of the amphibole variety, some of the fibre being as long as 8 inches.

---

The report of the Council of the Canadian Mining Institute for the year 1912, printed elsewhere in this issue, is a satisfactory record of progress. It is gratifying to note the steady increase in membership, which now is in excess of a thousand. The accessions during the year of 170 members, associates and student members, constitute an increase of nearly 20 per cent. on the membership returns of 1911. There could be no better indication that the value of the work of the Institute is both recognized and appreciated by the mining men of the Dominion. By the establishment of a branch in Southern Alberta last autumn the Institute is now represented by local organizations in all the principal mineral producing provinces, with the exception only of Nova Scotia, where, however, it is least necessary. The meetings last year were distinctly successful from every point of view, and the volume of transactions, which we understand, will be distributed shortly, will contain many papers of quite exceptional interest and importance.

---

A circular recently issued by the secretary of the Canadian Mining Institute contains the information that the next annual general meeting will be held in Ottawa. The provisional programme as published promises well. The subjects announced for discussion are for the most part of timely interest or have a practical significance. The meeting, we learn, is to be opened by H.R.H. the Governor-General, and the Rt. Hon. the Prime Minister has accepted an invitation to be the Instiute's guest of honour at the "annual dinner," at which he will speak.

## RESIGNS OFFICE OF PROVINCIAL ASSAYER.

With the close of 1912, Mr. Herbert Carmichael, of Victoria, ended a long period of service with the British Columbia Government, having resigned the office of Provincial Assayer so that he may give his time and attention wholly to his private interests.

On September 21st, 1891, Mr. Carmichael was appointed Government Analyst, and in the spring of the following year received the appointment of Provincial Assayer, the duties of both offices thus devolving upon him. At that time there was not an organized Department of Mines in the Province, nor any separate clerical staff to attend to the work connected with mining. The Provincial Secretary or another minister of the day acted as Minister of Mines, and his staff attended to whatever clerical work was requisite in that connection. The only technical advisers in respect of mining the Provincial Government then had were Mr. Archibald Dick, of Nanaimo, Inspector of Mines, and Mr. Carmichael, Provincial Assayer. From the time the Hon. John Robson, then Premier, was as well Minister of Mines, until the present there has been a very large expansion of the mining industry of the Province, and with it of necessity the organization and development of the Department of Mines

Prior to 1892 lode-mining was of very little importance in British Columbia, the total value of production up to that year, as on official record, having been less than \$300,000. The aggregate value to the end of 1912 is in excess of \$200,000,000, so that during his term of office Mr. Carmichael has seen the industry with which he has so long been officially identified make advances that, in so new a country, may fairly be described as tremendous. This is the aggregate value of lode minerals prodneed—not of all minerals—for the grand aggregate is now nearly \$330,000,000.

### An Interesting Incident.

As an interesting incident of by-gone years, it may be mentioned that one of the first lots of ore Mr. Carmichael had sent to him was some from Slocan district, forwarded by Mr. Frank Fletcher, long identified with Nelson. This was found to assay more than 3,000 oz. in silver to the ton, and notwithstanding that he got similar results from each test he made, the new Provincial Assayer signed the certificate with fear and trembling, for such rich galena ore until then had been unknown in British Columbia. To-day, and for many years, such an assay return, would cause no surprise. The banner year for work in the Assay Office was in 1897; there was nothing like it before, nor has there been since.

Mr. Carmichael, among many useful duties performed, was largely instrumental in getting the Bureau of Mines Act, 1895, passed, which Act he drafted. Under that Act, Mr. W. A. Carlyle was the same year appointed the first Provincial Mineralogist for British Columbia, and these two officials in January, 1896, began the organization of the Bureau of Mines. Early in 1898 Mr. Carlyle resigned, and was followed in the office of Provincial Mineralogist by the present occupant, Mr. Wm. Fleet Robertson, who took office on June 1st, 1898.

During many years of zealous performance of his official duties, Mr. Carmichael has made numerous friends throughout British Columbia, and these, while regretting that the Department of Mines is losing the efficient services of so good a chemist and so capable an officer, will wish him abundant success in his enterprises, several of which will hereafter fully occupy him.

# NOVA SCOTIA'S MINERAL PRODUCTION, YEAR ENDING SEPTEMBER 20th, 1912

Written for the Canadian Mining Journal
By H. B. Pickings.*

The year 1912 from a production standpoint has been for the mineral and allied industry of Nova Scotia a record year.

The coal production 6,800,000 tons was greater by half a million tons than the production of 1908 the previous record year. The large increase was due to a record production by the Dominion Coal Company and Nova Scotia Steel & Coal Co., in Cape Breton, and the resuming of operations at Springhill, when the Dominion Coal Company took over the mines of the Cumberland Railway and Coal Co. The Pictou County production was slightly less than in 1911, due to attention given by the Acadia Coal Co. to underground development and the changing of their power plant from steam to electricity, the electric power to be generated from coal at a central power station.

Since the closing of the Canada Iron Corporation mines at Torbrook in 1911 no iron ore has been mined in the Province. This company did, however, operate their concentrating plant, treating ore from their stock pile at Torbrook and they made a number of shipments. The iron-ore market has recovered from the low prices of 1911 and the Torbrook mines are being unwatered and will shortly be again in production.

The quantity of gypsum quarried was 350,000 tons, the greater quantity as in the past being from the quarries near Windsor, Hants Co. Extensive diamond drilling has been and is now being done on several of the gypsum deposits.

The gold production of 5,000 ounces falls far below the production of the previous year, and is many thousand ounces below the average yearly production of the Province, while the industry can not be said to be in a flourishing condition, the bullion produced does not do justice to the extent of the operations carried on, as at several districts serious attention was given to mine development and plant equipment, and no effort made to immediate production.

The production of 250 tons of manganese was all recovered from mine development by the Nova Scotia Manganese Co. at New Ross. This company directed all their efforts during the year to mine development, surface equipment and the construction of a road to tide water at the Avon River, the length of the road to be built being nine miles, of this seven miles has been completed. In the mine preparations have been made to commence stoping, and mining and shipping of ore will shortly be undertaken.

Shipments of tungsten concentrates totalling 15 tons were made from the property of the Scheelite Mines, Ltd., at Scheelite, Moose River, the concentrates being of particularly high grade, running over 72% tunstic acid. Development work has been continued at this property during the year.

The Barytes, Ltd., at Lake Ainslie commenced operating their new mill and produced 1,000 tons of manufactured barytes, shipments were made as far west as Winnipeg. No other barytes was mined.

The steel companies of the province, the Dominion Iron & Steel Co., and the Nova Scotia Steel & Coal Co. produced 415,000 tons of pig iron and 465,000 tons of steel ingots, both record productions. Limestone quarried for flux purposes was 550,000 tons.

The amount of coke made was 600,000 tons, an increase of 55,000 tons over the amount manufactured in 1911.

The output of the brick yards, 23,000,000, is about the same quantity as during the previous year. Several of the larger brick yards have been merged under the name of the Nova Scotia Clay Works, Limited, and preparations are being made greatly to increase outputs.

Building stone at 10,000 tons, drain pipe tile, etc., at 1,000,000 feet are about same as the production of 1911.

Other productions were moulding sands 1,200 tons, and sulphate of ammonia 5,200 tons.

Prospecting has been engaged in on iron, molybdenite, lead-silver, copper, oil-shale and other deposits, but while promising finds have in some cases resulted, no ore has been mined during the year.

The amount of iron ore imported into the province and reduced in the furnaces of the Dominion Iron & Steel Co., and the Nova Scotia Steel and Coal Co., was 880,000 tons.

The figures given above are all for the 12 months ended Sept. 30th, 1912, the fiscal year of the Nova Scotia Department of Mines ending on that date, and the figures for the calendar year therefore not being available at this writing, while some of the individual productions will for the calendar year vary slightly, but taken as a whole the production will be about the same.

# MINE RESCUE WORK IN CANADA*

By W. J. Dick.

In Canada as regulation of mines is a function of each province, the Federal Government has no authority to require operators in the several coal-mining provinces to make provision for mine-rescue aparatus. Neither has the Federal Government carried out any demonstration work in th use of such apparatus. Of the coal-producing provinces, British Columbia is the only one that requires rescue apparatus to be kept at coal mines.

The following is a short account, by provinces, of the nature and extent of mine-rescue work in Canada:—

### NOVA SCOTIA.

Ther are no government rescue stations in this province, nor is there any statutory provision for compulsory mine-rescue training and equipment at coal mines.

*Mining Engineer, Halifax, N.S.

*From Report of Commission of Conservation.

Nevertheless, a number of the most important mines have well equipped rescue stations and a large body of men trained in the use of breathing apparatus.

**Dominion Coal Company.***—The Dominion Coal Company, have in the past, suffered severe lsses through fire, both above and below ground. In 1903, a fire occurred in Dominion No. 1 mine, and, in 1906 a fire broke out in the pit bottom of the Hub colliery. In both cases, the mine had to be flooded before the fire could be extinguished. In order to guard aginst similar possible occurrences,, an efficient fire fighting organization and equipment were established. Only that portion of the equipment and organization which relates to breathing apparatus will be considered in this description.

In 1908, the Central Rescue station was constructed and equipped near No. 2 colilery. Its central position in relation to the surrounding mines, indicated it as the most desirable. When erected, this station was, with the exception of the United States Government station a Pittsburg, the only one of its kind on the North American continent. It is a substantial brick building with concrete floor, and contains four rooms, viz.: main or apparatus room, emergency hospital and dressing room, office and store-room.

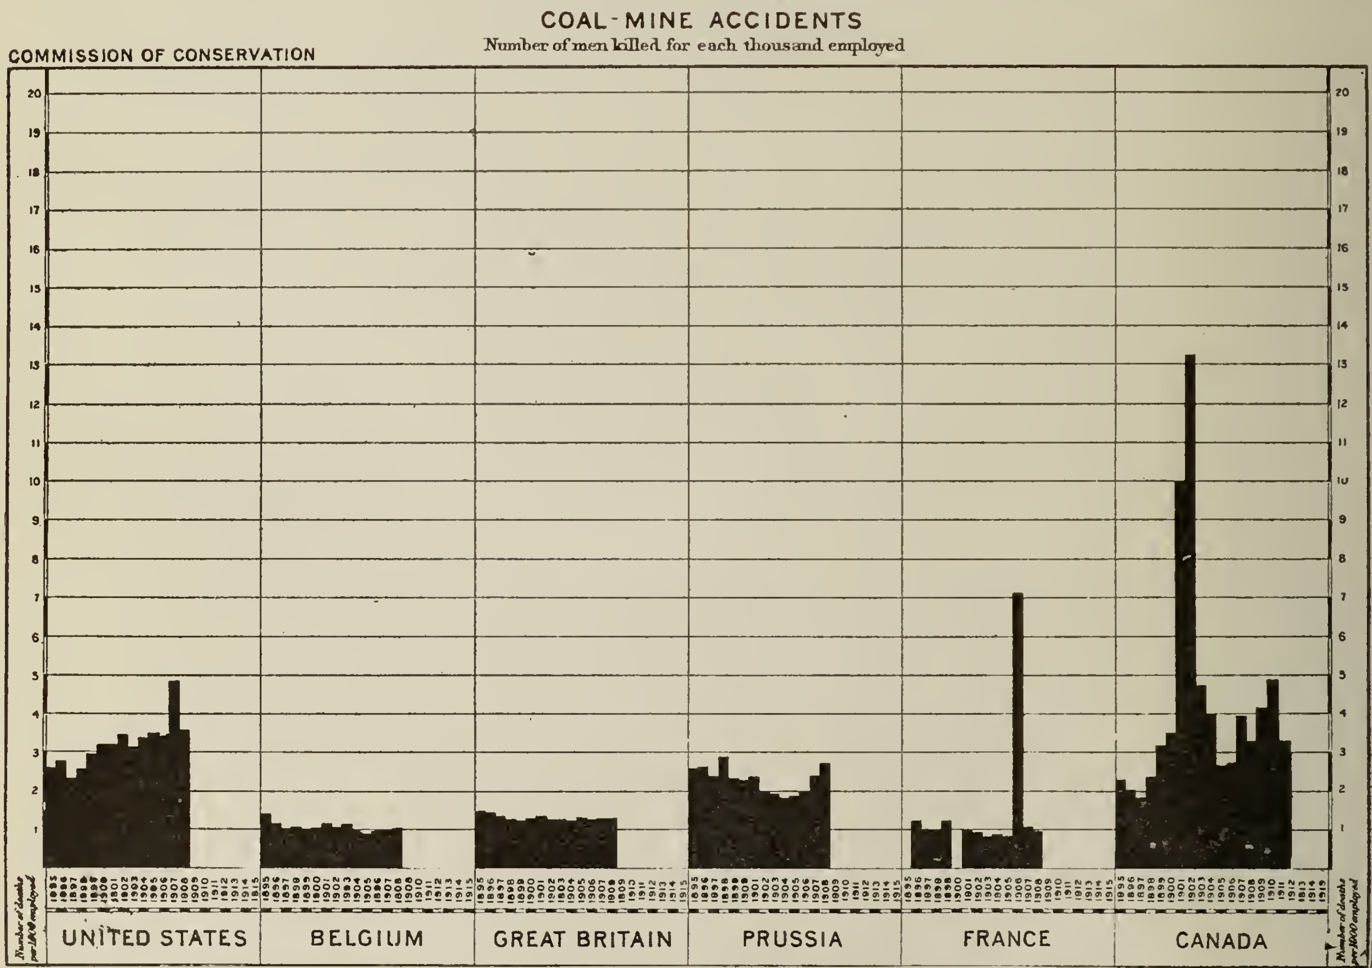
The equipment consists of thirty-six Draeger apparatus, forty-two electric hand-lamps, one Bratt resuscitating apparatus, one pulmotor, one electrically-driven oxygen-refill pump and one hand-power oxygen-refill pump, one Koenig smoke-helmet, one wheel stretcher with oxygen flask and mask complete for bringing injured men out of an irrespirable atmosphere, and a sufficient supply of oxygen and potash cartridges. The electric hand-lamps are charged at the station and kept always ready for use. The station is connected by telephone, with al the collieries and with the instructor's residence.

One end of the rescue station is fitted up as an emergency hospital and dressing room. It contains a wash-basin, spring couch, table and rubber sheet. First-aid requisites, blankets, stimulants, etc., are also kept on hand. In additon to the ordinary stock in the store-room, eight canaries are also kept available for the purpose of testing for carbon monoxide during mine-rescue work.

Adjoining the station is a smoke chamber where the men are trained to work in an irrespirable atmosphere This is a rough, wooden shed, consisting of an observation corridor divided from the main building by a partition with glass windows. The smoke chamber proper has no windows, and has a fire grate in one corner in which materials are burned to make a dense smoke. For exercising the men during trainig, there are two weight lifting machines, consisting of a rope passing over a pulley and attached to a 45 pound weight.

Men training in the use of breathing apparatus, enter the smoke room wearing the apparatus and carrying electric lamps. After performing a certain amount of work, each man is examined as to his behaviour under physical strain and his suitability for this class of work is thus determined.

In addition to the apparatus at the Central station, auxiliary apparatus are kept at some of the outlying collieries. These are intended for use by the colliery rescue corps pending the arrival, if necessary, of a detachment from the Central station.



*In this description of the mine-rescue equipment of the Dominion Coal Company, free reference has been made to the article on "The Fire Fighting Organization and Equipment" of these collieries, written by F. W. Gray, Assoc. M. Inst. M.E., and published in the Canadian Mining Journal.

Each colliery has either two or three rescue corps, consisting of men who are resident at the colliery and acquainted with the workings. These men are chosen because of their knowledge of the underground workings, ventilation and position of their knowledge of the air roads, pipe lines and connections. A necessary preliminary to their selection is that they must be passed upon by the instructor as being suitable for the work. The names of the men composing the corps and the period for which they are detailed for duty are posted in the firemen's hall, near the apparatus. As far as possible, the corps are arranged in such a way that the trained men at one colliery shall not all be underground at the same time.

The instructor makes periodical visits to all the collieries having rescue apparatus and exchanges the colliery apparatus for others from the Central station. This is done in order that the apparatus may always be in good working order.

The company intends, also, to install a sub-rescue station at New Waterford to serve the Lingan collieries. This equipment is to consist of ten Draeger apparatus with spare oxygen cylinders, one hand power oxygen refill pump and one pulmotor. It is also the intention of the company to install a rescue station at the Springhill collieries. It will consist of ten apparatus, one refill pump and one pulmotor together with the necessary oxygen tanks and accessories.

tached; ten electric hand lamps, one oxygen-refill pump, one Bratt resuscitating apparatus, and a sufficient supply of oxygen and absorption cartridges.

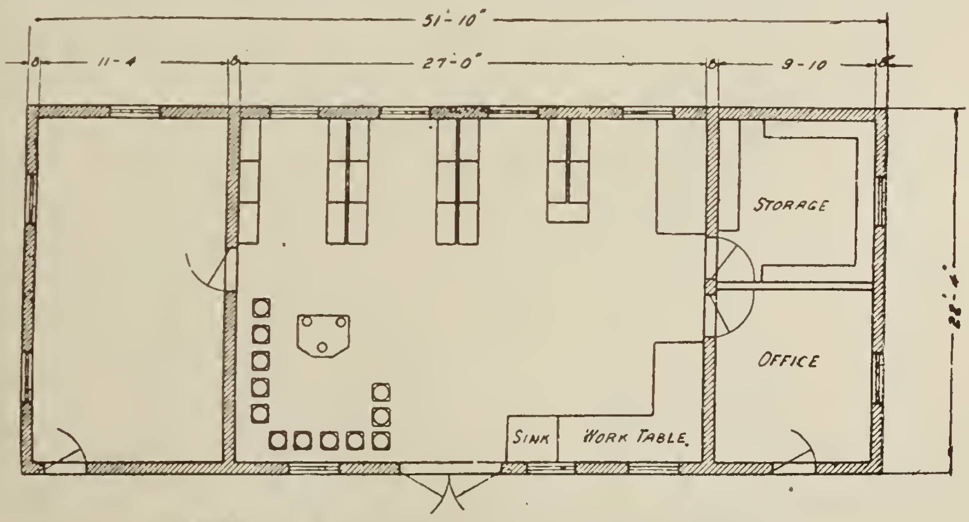
The rescue corps are made up of six men each. It is planned to give each corps a complete course of training—consisting of ten lessons—immediately after volunteering, and, then, have them meet once a month that they may be kept familiar with the apparatus and be able to answer a call instantly.

**Nova Scotia Steel and Coal Company.**—This company has a rescue, fire and first-aid station. It was formerly in a room in the general office building, but is now in a railway car. This car is always held in readiness to go to any of the collieries owned by the company or to any colliery in the province with which rail connections can be made. It is an ordinary passenger car and is divided into three sections.

Car Section No. 1.—This section is fitted and furnished for the accommodation of the rescue crew.

Car Section No. 2.—This section is fitted with:

16 sets of rescue apparatus.
24 oxygen cylinders.
2 oxygen-refill pumps.
1 pulmotor.
2 dozen electric safety lamps.
1 electric charging device for charging electric lamps.



**PLAN OF CENTRAL RESCUE STATION, SHOWING APPARATUS ROOM AND EMERGENCY HOSPITAL**

The company has now a large number of men trained in the use of the apparatus. It has been successfully used on several occasions, notably at Sydney Mines and at Stellarton. Apart from the rescue work, there are a number of men trained in first-aid and ambulance work, there being properly fitted ambulances to serve all the collieries.

**Acadia Coal Company.**—This company has a training station in which the men are instructed in the use of portable breathing apparatus. The station consists of a building 20 feet by 40 feet, in which the aparatus is installed and lessons are given in its use in a breathable atmosphere. The smoke room, where the men test the apparatus before going into the mine, is about the same size as the station. The company intends to place a number of obstacles in the smoke room to simulate the interior of a mine, so that the men may be trained under conditions similar to those that exist underground.

The equipment consists of ten helmet type Securitas apparatus, each with two hours' oxygen supply at-

1 Draeger oxygen reviving trunk.
6 ordinary respirators.
Blue print plans of all the collieries.
1 set of portable telephones.
Canaries for gas testing purposes.

Other accessories which are necessary in the event of a mine explosion, are also stored in the car. Section 2 also contains stretchers, splints, oil, restorators, and drugs of all kinds which might be necessary in case of accident.

Car Section No. 3.—This section contains fire reels, hose, fire buckets, ladders, axes, saws, fire extinguishers and all the necessary equipment for use in case of fire. The car is furnished with blankets, cooking stove, and all articles necessary to enable the crew to live on board the car for short periods of time.

The types of rescue apparatus used are, fifteen of the Draeger helmet-type and one of the Ever-Ready mouthpiece type. These have an oxygen capacity for about two hours' effective work.

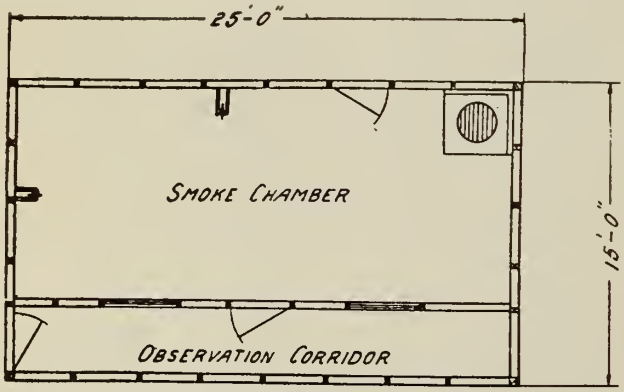
Of the twenty-four oxygen cylinders, only seven are carried in the car, the others being stored as an emergency supply. The capacity of these cylinders is 100 cubic feet of oxygen at a pressure of 125 atmospheres. In connection with the breathing apparatus, a smoke house is constructed for the purpose of giving the men practice in using the apparatus in an irrespirable atmosphere. The smoke house is centrally situated and is built in such a way that while they are at work in the unbreathable atmosphere, the men can be observed by the head trainer from the passage way.

There are at present about forty men, including all the officers in connection with the collieries, who are trained in the use of the rescue apparatus. In addition to this number, twenty-four officers of the company hold certificates of proficiency in giving first-aid to the injured, granted by the St. John's Ambulance Association.

In connection with this work there are also ambulances, stretchers and blankets at each colliery, while in the rescue car there is a first-class ambulance fully equipped with every convenience for the conveyance of injured men from the car to the hospital or their homes.

## ALBERTA.

In this province, no statutory provision is made for compulsory mine-rescue training and equipment at coal mines. The opinion seems to be that it is better to have one or more central stations with officials in charge of the stations who will be responsible for the upkeep of the apparatus.



PLAN OF SMOKE CHAMBER

*By Courtesy of F. W Gray, Dominion Coal Company*

At present. there is only one mine-rescue station in Alberta. This is a temporary station situated at Blairmore and is available for all the mines in the Crow's Nest Pass district. An additional rescue station is now being erected at Lethbridge, and, in a short time, a third will be established at Kipp. The Blairmore station has only been in operation since March, 1912. One-half of the cost of the equipment and operation of this station will be borne by the Government of Alberta, and one-half by the different operators in the district. It is expected that, within a short time, a railway car will be fitted up with rescue apparatus and moved from mine to mine.

The station in use at present consists of three rooms, each 24 feet by 14 feet; the apparatus is kept in one; another room is fitted up as an office and lecture room; and the third is a smoke chamber.

The station is under the charge of a superintendent holding a mine manager's certificate. The training, which occupies six days, is divided into the following sections:

First day—Description of apparatus by superintendent and taking apart and putting together of apparatus by persons being trained.

Second day—Lecture on apparatus for one hour and wearing of apparatus in smoke chamber for one hour.

Third day—Wearing of apparatus in mine for one and a half hours and further lecture on apparatus.

Fourth day—Wearing of apparatus in mine and in smoke chamber for two hours.

Fifth day—Wearing of apparatus in mine for two hours.

Sixth day—Wearing of apparatus in mine for one and a half hours, and in smoke chamber one hour.

This training is varied slightly according to the discretion of the superintendent. While in the smoke chamber, a considerable amount of work is done in sulphur smoke, such as building stoppings, putting up and taking down brattice, and general work as nearly as possible similar to that which would be required to be done in a mine during rescue work.

While in the mine, the wearers of the apparatus travel up a roadway pitching about 40 degrees, for a distance of about 450 feet and come out at the surface. The authorities have not yet decided upon the exact routine of training work and may vary this considerably. After a man has gone through six days' training, it is the intention to bring him back at the end of three months to undergo another training, and again, at the end of a further three months, after which he will, if judged to be satisfactory, be granted a certificate showing that he is capable of doing rescue work in a mine after an explosion.

Primarily, the training work has been considerably handicapped by the difficulty in obtaining a sufficient supply of oxygen and soda. In order to overcome this, however, it is the intention to carry on hand a stock of 3,000 cubic feet of oxygen at a pressure of 120 atmospheres, and 1.500 lbs. of caustic soda.

At this station there are eleven Fleuss apparatus of the two-hour type and six of the one-hour type. This will probably be increased to fifteen of the two-hour type and ten of the one-hour type.

## BRITISH COLUMBIA.

The Coal Mines Regulation Act, 1911, makes provisions for rescue apparatus at mines, as follows:

"There shall be established by the owner, agent or manager of every colliery such number of oxygen helmets or some form of mine-rescue apparatus as may be approved by the Minister of Mines.

"Such mine-rescue apparatus shall be constantly maintained in an efficient and workable condition, and shall in all cases be so stored or placed in or about the mine as to always be available for immediate use.

"The Lieutenant-Governor-in-Council may from time to time establish mine-rescue stations for the purpose of supplementing, in case of need, the colliery installations of mine-rescue aparatus, and also for the purpose of training the holders of certificates of competency under this Act in the use of such mine-rescue apparatus as may be approved by the Minister of Mines; and it shall be incumbent on the owner, agent or manager of every operating mine to have all certificated officials who are physically fit, and not less than three per cent. of such number as the Chief Inspector of Mines may deem sufficient, of the workmen, trained in the use of such established mine-rescue apparatus:

"Provided that in cases of emergency such stations shall be available for the use of any trained corps of mine-rescuers, duly qualified medical practitioners, or corps trained in the work of first aid to the injured, subject, always, to the order of an Inspector of Mines."

Although this Act has only been in force a little over a year, the operators, as well as the Government, are doing all in their power to lessen the number of fatalities incident to mine explosions and mine fires in so far as this can be accomplished by trained men equipped with suitable breathing apparatus.

The Government of British Columbia has secured sites for rescue stations at Fernie, in the Crow's Nest district, and at Nanaimo, Vancouver Island. Tenders have been called for the erection of the buildings and they will be completed at an early date. The illustration facing page 28 shows the plan and elevation of these buildings.

The Government owns the following apparatus:

12 sets of two-hour, 1910 model, helmet type Draeger apparatus.

8 sets of one-half hour, mouth-breathing type Draeger apparatus.

4 pulmotors.

42 oxygen tanks, of 100 cubic feet capacity each.

14 electric safety lamps, together with all necessary accessories and spare parts.

They have also under order two sets of two-hour, 1911 model, mouth-breathing type Draeger apparatus and sufficient material to convert the present 14 sets of 1910 model, helmet-type into mouth-breathing type. These apparatus will thus be available either as helmet or mouth-breathing apparatus. Two stretchers equipped with oxygen breathing apparatus and 16 trunks for storing and shipping the apparatus, are also on order.

The present distribution of this apparatus is as follows:

**Nanaimo—**
- 4 sets of two-hour apparatus.
- 2 sets of one-half hour apparatus.
- 1 pulmotor.
- 12 oxygen tanks.
- 1 oxygen pump.
- 4 electric safety lamps.

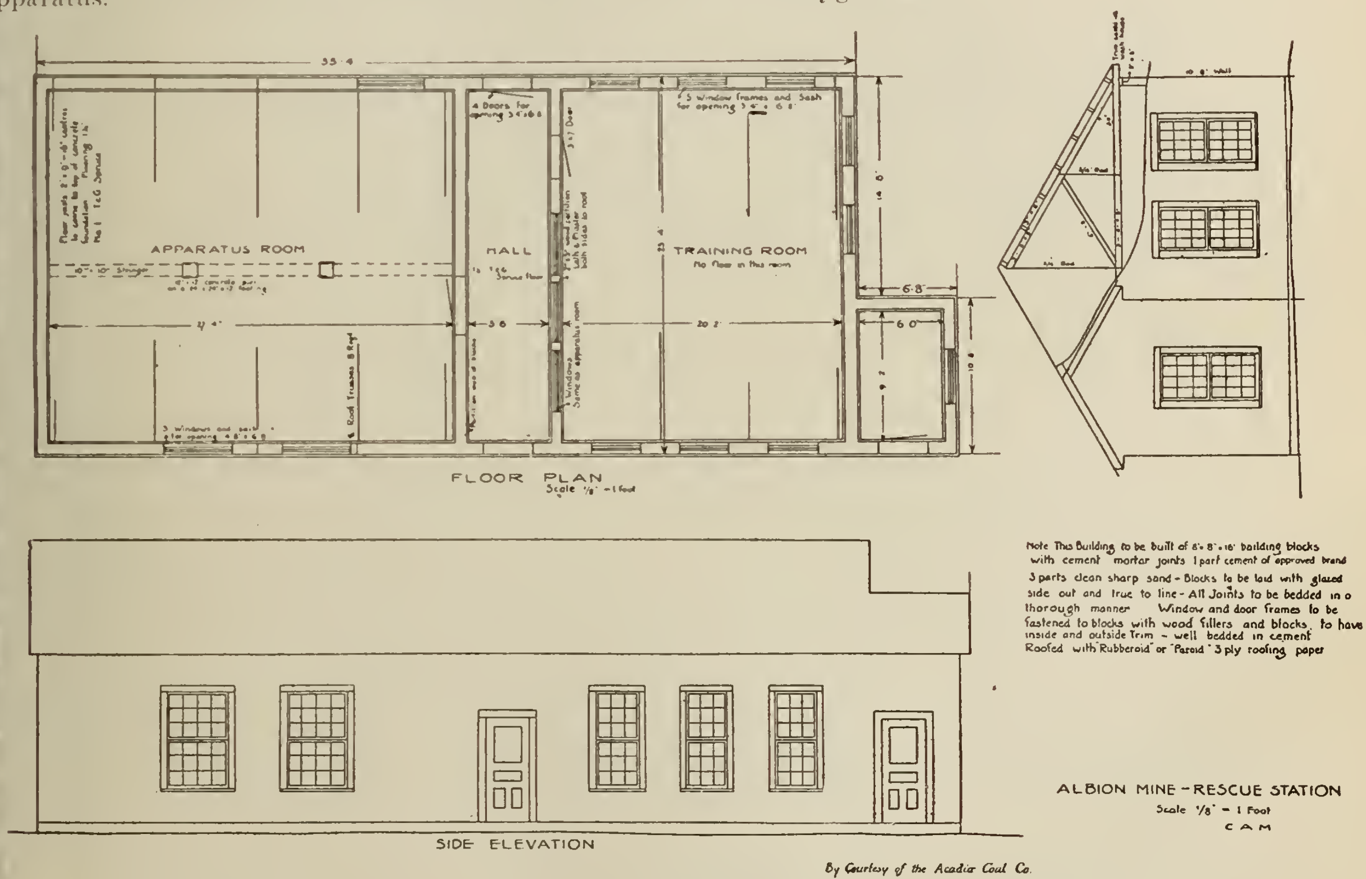
**Cumberland—**
- 4 sets of two-hour apparatus.
- 2 sets of one-half hour apparatus.
- 1 pulmotor.
- 12 oxygen tanks.
- 1 oxygen pump.
- 4 electric safety lamps.

**Hosmer—**
- 4 sets of two-hour apparatus.
- 2 sets of one-half hour apparatus.
- 1 pulmotor.
- 14 oxygen tanks.
- 1 oxygen pump.
- 4 electric safety lamps.

**Middlesboro—**
- 4 sets of two-hour apparatus.
- 2 sets of one-half hour apparatus
- 1 pulmotor.
- 4 oxygen tanks.
- 2 electric safety lamps.

This apparatus is supplementary to the equipment of the coal companies and at present is taken care of by the Western Fuel Company, at Nanaimo; the Canadian Collieries (Dunsmuir), Ltd., at Cumberland; the Hosmer Mines, Ltd., at Hosmer, and the Nicola Valley Coal & Coke Co., Ltd., at Middlesboro.

**Mining Companies and their Equipment.**—All the operating companies own, or have on order, oxygen apparatus of some type, and some companies own very creditable stations for training purposes.



PLAN OF ALBION MINE-RESCUE STATION, ACADIA COAL CO.

Western Fuel Co., Nanaimo.—This company erected the first station in the province. It was opened in the autumn of 1910, and, since that time, 62 employees of the company have taken a course of training in it and have been awarded certificates of competency. These employees have been formed into 12 corps.

This company's station is of frame construction on concrete foundation and is covered with corrugated iron. The inside is finished in hard wall plaster, its dimensions being 24 feet by 48 feet. It consists of a smoke room and work room, the latter containing the cases for the apparatus.

The apparatus consists of

4 sets two-hour, 1907 model, helmet-type Draeger apparatus.
4 sets two-hour Fleuss (Proto) mouth-type.
3 sets one-hour Fleuss (Salvator) mouth-type.
1 pulmotor.
12 oxygen tanks.
1 oxygen pump.
4 electric safety lamps (Draeger type).
6 electric safety lamps (Fleuss type).

The work necessary to obtain a certificate consists in becoming familiar with the principle and construction of the apparatus, in assembling and dissembling the same and in the use of the pulmotor.

Then a team of four men must perform the following two-hour schedule of work not less than seven times, in the smoke room filled with either sulphur or formaldehyde fumes:

1. 15 laps around the smoke room, travelling over the overcast and crawling through the tunnel, which is 3 feet high and 4 feet wide.

2. Hang 8 yards of brattice cloth over the overcast, and erect 4 yards of board brattice in the tunnel, all material being brought over the overcast.

3. Make 10 laps around the smoke room over the overcast and through the divided tunnel, take down the board and cloth brattice, placing it where found.

4. Each pair of men to carry a dummy on stretcher, weight 150 lbs., twice around the smoke room, over the overcast and through the tunnel, using both the Sylvester method and Draeger pulmotor for resuscitation purposes.

5. Erect a board regulator in the centre of the tunnel area 18 inches by 18 inches, each pair of men to take the dummy without the stretcher once around the room over the overcast and through the regulator; then each member of the crops to make 10 laps without the dummy.

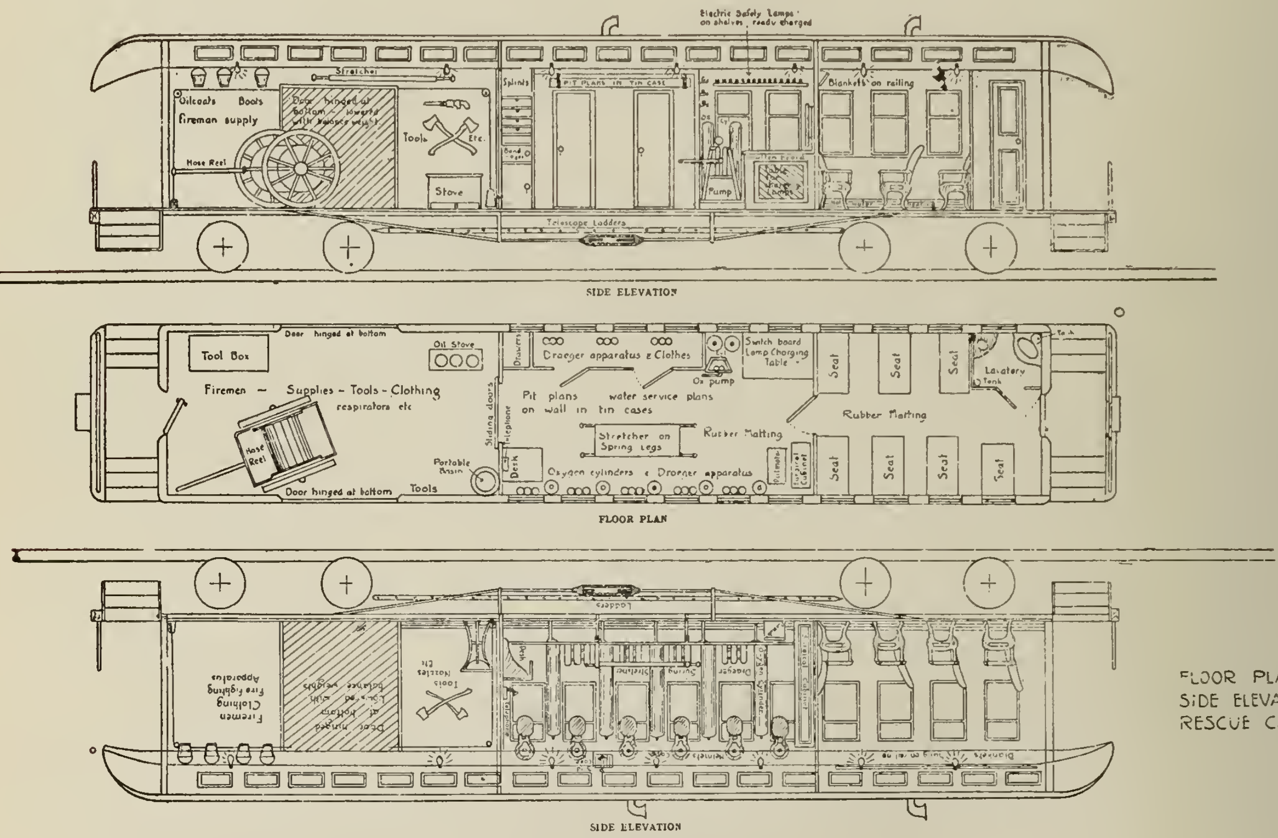
6. Take down the regulator and erect in the middle of the tunnel a brick stopping 1½ bricks thick, carrying all material over the overcast. Take down stopping, carrying material back to place where found and piling up neatly.

7. The top of the tunnel is then raised against the wall to prevent crawling, and as many laps made around the smoke room and over the overcast as can be made within the two-hour limit.

A record is kept of each man's work, including amount of oxygen upon entering, and upon coming out, length of time in the smoke room, and his general condition when he comes out.

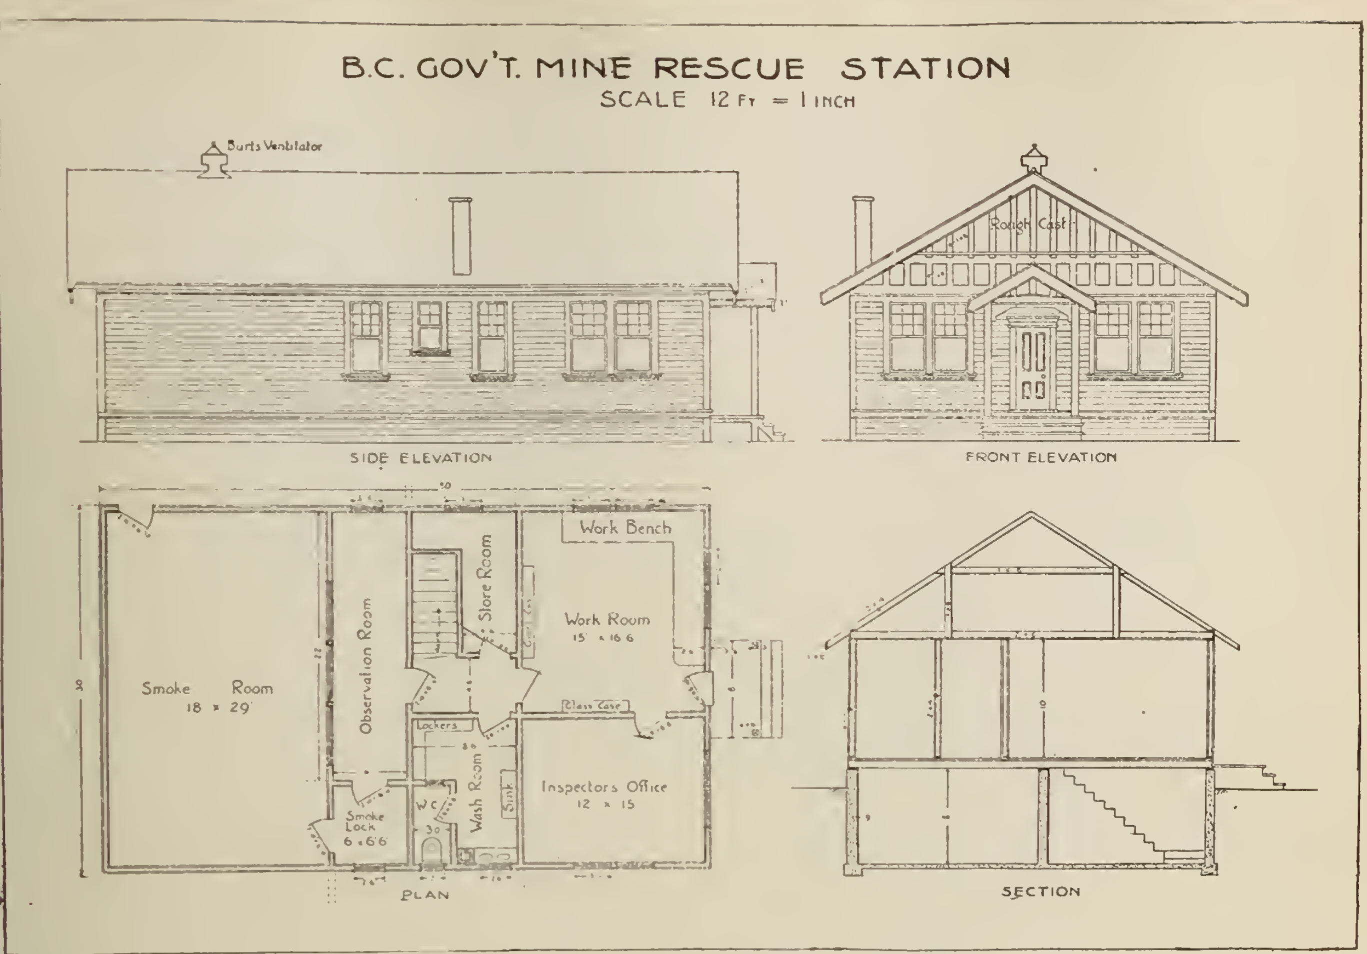
The lamp used is either Wolf safety lamp or Electric safety lamp. Each person holding a certificate must report for practice once every month. An instructor is in charge of the station and in daily attendance. The illustration facing page 29 shows this station.

Canadian Collieries (Dunsmuir), Ltd., Extension Colliery, Extension.—This company has just completed a station of frame construction 25 feet by 53 feet, which



FLOOR PLAN & SIDE ELEVATION of RESCUE CAR

PLAN OF RESCUE CAR, NOVA SCOTIA STEEL & COAL CO.



*By Courtesy of B. C. Department of Mines* PLAN OF RESCUE STATION, GOVERNMENT OF BRITISH COLUMBIA.

contains a smoke room, observation room, work room and dressing room.

The course of training consists of preliminary work to give the candidates an introduction to the apparatus, and the method of wearing it, travelling through the various openings in the smoke room, without smoke. This is followed with such practical work as fixing brattice, both cloth and board, cleaning up caves, building stoppings, brick and board, and a stretcher drill in which dummy is rescued from place of danger and carried to place of safety. Mr. J. H. Cunningham, who has taken a course of training at the United States Rescue station at Seattle, Wash., will be the instructor.

The equipment at this station consists of:

4 sets, two-hour, 1910 model, helmet-type Draeger apparatus.
1 oxygen pump.
4 oxygen tanks.
4 electric safety lamps( Draeger type).

---

# THE INTERMITTENT SYSTEM IN CYANIDATION

By Leon P. Hills.*

The popularity of the continuous system in direct cyanidation is, I believe, an unfair verdict against the intermittent system. The former undoubtedly sprang from the difficulties encountered in the latter in promptly effecting a condition of suspension in the charge to be agitated, clogging of pipes, etc. All of these difficulties can be wholly obviated at present, one means being by the use of the agitator hereinafter described.

Theoretically, the charge system surpasses the continuous. The latter is, by its very nature, inefficient. Assume a series of 100-ton tanks, with a flow of 10 tons per hour. Consider the efflux from the first tank for any given hour. That 10-ton portion is composed of, approximately:

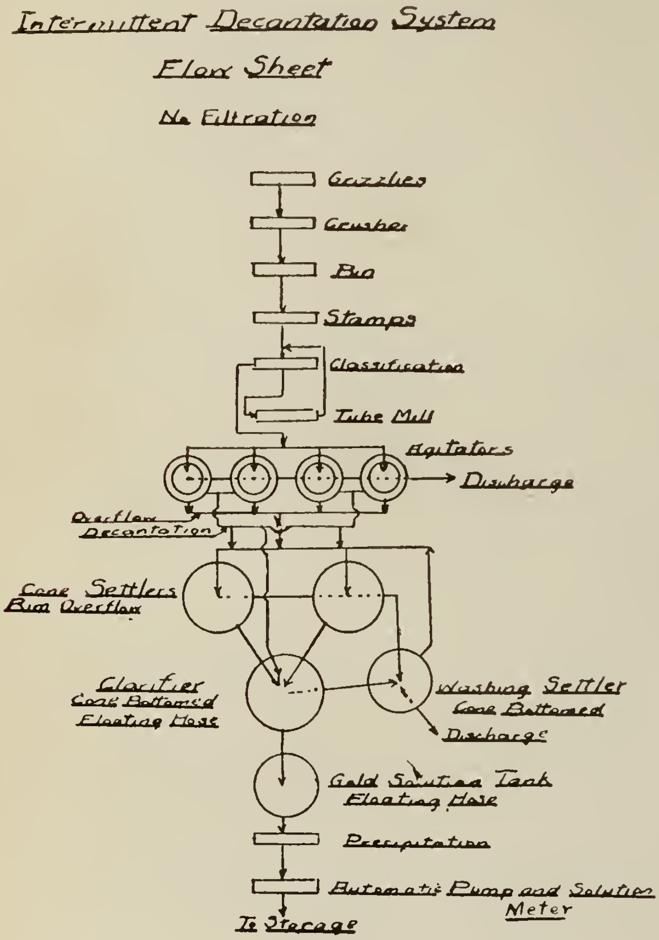
0.090 tons of the influx of the given hour.
0.825 tons of the first preceding hour.
0.751 tons of the second preceding hour.
0.683 tons of the third preceding hour.
0.621 tons of the fourth preceding hour.
0.565 tons of the fifth preceding hour.
0.513 tons of the sixth preceding hour.
0.466 tons of the seventh preceding hour.
0.424 tons of the eighth preceding hour.
0.386 tons of the ninth preceding hour.
0.351 tons of the tenth preceding hour.

the remaining 3½ tons in diminishing portions back to the initial inflowing 10 tons. The great bulk of the pulp receives exceedingly long treatment, the time of treatment of different portions varying between wide limits.

*Manager United Mines Co.'s Cyanide plant, Tuolumne, Cal. Article from the Colorado School of Mines Magazine.

Also the heavier and coarser particles make the most rapid transit through the series, thus that portion requiring the longer treatment gets the shorter treatment. The ideal system, wherein the pulp receives the exact treatment required to perfect extraction, can be closely approximated in the intermittent system.

The accompanying flow sheet illustrates an intermittent decantation system for which the following merits can be reasonably claimed: Simplicity, cheapness of installation, economy of power and labor, low cost of maintenance, flexibility of operation.



The agitator is the chief feature of this system, and insures reliability of operation. It is a modification of the Pachuca, the central fixed column being surrounded by a vertically adjustable column of a few inches greater diameter. This outer column, by means of a screw at the top of the tank, may be moved from a position where the lower end of the column is in contact with the sides of the cone, to any predetermined point above that, the upper extremity of the column always being below the surface of the solution. During the time agitation is suspended and settling is taking place the outer column is in its lowest position, thus excluding the pulp from settling around the inner column and air jet. To start agitation turn the air on, which will institute circulation of solution down between the two columns and up through the central column, whereupon the outer column is raised, allowing the pulp to enter into the circulation. This agitator has been subjected to all kinds of tests and never failed to get the pulp into a condition of suspension and without the aid of additional air.

In the system under consideration a thickener to precede the agitators is not necessary. The agitator is provided with a baffle which gives a circumferential quiet zone when pulp is being run in and when agitation is taking place, the overflow going to cone settlers. When a charge is sufficiently thickened in the agitator, the pulp is switched to another agitator, and agitation started in the charged tank. During agitation barren solution may be run in to lessen the gold contents and also to vitalize the solution in the tank.

The extraction being completed, the outer column is screwed down, agitation suspended, pulp settled, solution decanted, and washes repeated as many times as is advisable, depending on the richness of the ore. The settlings from settlers and clarifier are drawn off intermittently to washing settler, or agitator, and washed.

In this system exists the condition that the finer pulp, in which the extraction is rapid, receives the short treatment and the heavier and coarser pulp receives longer treatment.

# THE CANADIAN MINING INSTITUTE

## THE COUNCIL'S ANNUAL REPORT

The following is a copy of the report of the Council of the Canadian Mining Institute for the year 1912, to be presented at the annual meeting at Ottawa on March 5th, next:

The Council has much pleasure in submitting the following report of the work of the Institute for the year ending December 31st, 1912:

### MEETINGS.

The fourteenth annual general meeting, held in Toronto on March 6th, 7th and 8th, was notably successful, the large attendance of two hundred and seventy-four, or, approximately, twenty-five per cent. of the present membership, being a specially gratifying feature; while the presence also of a number of distinguished engineers and geologists from the United States, and one from Great Britain, many of whom took a prominent part in the proceedings, contributed materially to the interest and success of the occasion. At the close of the meeting the visitors were afforded the opportunity of visiting the mines of the Porcupine and Cobalt districts, under the auspices of the Institute.

The first of what is hoped will be regular series of semi-annual, or Western meetings, was held in September in Victoria, B.C., and in Frank, Alta. The papers presented at these meetings were productive of interesting discussions, and the Council has every reason to believe that Western members both realize and appreciate the advantage of the innovation.

Other meetings under the auspices of the respective branches have been held at Sherbrooke and Montreal, in Quebec, Cobalt, Porcupine, Kingston, and Toronto, in Ontario; at Lethbridge, in Alberta, and at Vancouver, in British Columbia.

### BRANCHES.

The organization was effected in September, of the Rocky Mountain Branch, and in December, of the Ottawa Branch. To the former, members resident in southeastern British Columbia and southern Alberta as far east at Medicine Hat, will be attached, although provision is made that the British Columbia members shall as well continue to be associated with the Western Branch.

Proposals were under consideration during the year for the affiliation of the provincial mining societies of Nova Scotia with the Institute, and the President specially visited Halifax last spring to discuss the project. It was found, however, that satisfactory arrangements could not be made at the present.

### PUBLICATIONS.

The aim of the Council is to raise the standard of the Institute's publications to the highest possible level, and to this end all papers submitted for publication have been critically scrutinized, and those only accepted that appeared to the Publication Committee to contain information of real value to members. Some additional expense, however, has been incurred in securing a better grade of paper-stock for use in the printing of the volume of the transactions, and particular care has been taken to ensure that the half-tone illustrations shall be satisfactory. In view, however, of the considerable recent advances in the cost of printing, the Council decided that economy might be best effected by discontinuing the practice of printing papers in advance form in the Quarterly Bulletin, and henceforward separates of papers will only be supplied upon direct application.

The Secretary has completed the compilation of a General Index of Volumes I to X, inclusive, of the Journal of the Institute, and has included therewith summaries of the papers contained in these volumes, the majority of which are out of print. This work is now in press, and will be ready for distribution early in the spring. It is proposed to offer it on sale to members at practically the actual cost of production.

### MEMBERSHIP.

The Council would particularly direct attention to the gratifying fact that the membership, inclusive of all classes, now numbers over one thousand, the actual number being 1,035. The accessions during the year were as follows:

| | |
|---|---|
| Ex-officio | 6 |
| Members | 127 |
| Associates | 34 |
| Students | 3 |
| Total | 17 |

The losses by death, resignations, and removal were as follows:

| | |
|---|---|
| Deaths | 5 |
| Resignations | 18 |
| Removals | 26 |
| Total | 49 |

### LIBRARY AND READING ROOM.

The accessions to the library represent 136 volumes. The library and reading-room have been used freely during the year, both by members visiting headquarters and by strangers to whom the courtesy has been extended.

### STUDENTS' COMPETITION AND AWARDS.

Ten papers were submitted by student members in competition for the Institute's awards. The judges have recommended that a prize of twenty-five dollars be awarded to E. Futterer for his paper entitled "The Champion Mine"; while Mr. J. C. Jones' paper on the "Joplin District," is given honourable mention.

### GENERAL.

In conclusion, it is gratifying to be able to state that the affairs of the Institute are now in a more flourishing condition than at any previous time in its history. The membership, as already stated, is increasing steadily; organization by the establishment of branches throughout the country is being perfected; the publications are vastly more valuable than in the past, and, in general, the Institute is growing in strength and usefulness.

# THE INTERNATIONAL GEOLOGICAL CONGRESS

On Saturday, January 18th, Mr. G. G. S. Lindsey, speaking before the Toronto Branch of the Canadian Mining Institute, gave a very interesting outline of the work of the Twelfth International Geological Congress, and of the preparations being made for the Canadian meeting next summer. The visitors, Mr. Lindsey pointed out, are to be officially the guests of the Dominion and Ontario Governments, of the Royal Society of Canada, and of the Canadian Mining Institute. In reality, however, other Provincial Governments and several transportation corporations will help to bear the large burden that the reception of such a number of distinguished visitors implies.

The founding of the Congress was inspired, continued the speaker, by the collection of geological maps and sections from various regions of the Continent, as well as from many countries of Europe, for display at the International Exhibition in Philadelphia in 1876. The advantage of such comparative study so deeply impressed visiting geologists that at the annual meeting of the American Association for the Advancement of Science, held in Buffalo, August, 1876, a committee was appointed to arrange for an International Congress of Geologists at the 1878 Paris Exhibition. It may be noted here that Dr. T. Sterry Hunt was secretary of this first committee—the Comite Fondateur of 1876, and that at the first session of the Congress (1878) Messrs. A. R. C. Selwyn, F.R.S., T. Sterry Hunt, and Paul de Caze were the Canadian delegates.

The records of subsequent meetings, which are usually held every three years, are shown in the following table:

**Number of Members, Delegates, Vice-Presidents and Countries Represented at Each Congress.**

| Country, Year. | Members. Enrolled. | Attdg. | Del. | Vice-Pres. | Rep'd. |
|---|---|---|---|---|---|
| France, 1878 | 310 | | 7 | 18 | 23 |
| Italy, 1881 | 420 | 224 | 23 | 19 | 23 |
| Germany, 1885 | 455 | 258 | 15 | 20 | 22 |
| England, 1888 | 337 | 140 | 68 | 22 | 25 |
| U. S. A., 1891 | 546 | 251 | 39 | 31 | 24 |
| Switzerland, 1894 | 401 | 273 | 18 | 15 | 20 |
| Russia, 1897 | 1037 | 704 | 139 | 40 | 27 |
| France, 1900 | 1016 | 461 | 80 | 46 | 31 |
| Austria, 1903 | 664 | 393 | 39 | 25 | 30 |
| Mexico, 1906 | 707 | 321 | 83 | 27 | 33 |
| Sweden, 1910 | 857 | 625 | 262 | 74 | 36 |

The members of the Congress are usually professional geologists, or persons occupied in an allied profession. Amateurs, however, are welcomed, and their work has often been of great importance. Delegates are members of the Congress who have been specially appointed to represent a government, university, or society. Vice-Presidents are members of the Congress, usually delegates, elected at the first meeting of each session to represent their country on the Council of the Congress.

Geologists from every quarter of the globe attend the Congress. The word "International" in the title was well chosen since a remarkable number of nationalities are represented at each Congress.

The members may be divided roughly into three classes:

1st. Professors and teachers from the leading universities, colleges, and technical schools.

2nd. Officers of government geological surveys or equivalent organizations.

3rd. Geologists and mining engineers in private practice.

The Congress is governed by a Council constituted as follows:

(a) Members of the Organization Committee to Twelfth Congress.

(b) Presidents of geological societies.

(c) Directors of important geological surveys.

(d) Members of the "Bureau" (i.e., Vice-Presidents of other office holders elected by the members at their first meeting).

(e) Members of the Congress whom the Council may add to its number.

The "Bureau" is made up of persons whose names, submitted by the Council, have been approved by the members at the first meeting of the Congress. It is charged with the arrangements of the orders of the day for the meetings.

An Organization Committee, or an Executive Committee, is appointed for each session by the Government or institution whose invitation for the ensuing session has been accepted at the previous session, and local arrangements are left to these local organizations. The General Secretary of a session is responsible for the management of Congress affairs until next sesion has met and hi successor has been duly appointed.

The prime object of the International Geological Congress is the advancement of knowledge both in the field of pure geological science and in its application to the arts and industries. The principal means to this end are:—

1. Meetings. 2. Publications. 3. International Committees. 4. Excursions. 5. Prizes.

1. The meetings are held every three years in different countries, and are attended by members represnting very civilized nation. The leading countries, societies, and universities are represented by specially appointed delegates. Papers are read and discussed bearing on topics of scientific or economic importance. These topics are selected in advance so that every member interested is given a chance to take part.

2. Publications.—The transactions of the Congress, containing the more important papers and discussions, and a general report, are published as soon after the session as possible. The Transactions of the Eleventh Congress contained 1,413 pages. Two quarto volumes and a large atlas on the iron ore resources of the world were also brought out, together with another large quarto.

3. The International Committee deal with such questions as the standardization of nomenclature, general geological maps, etc., etc.

4. Excursions have become the outstanding feature of the sessions. They are conducted at small expense to the individual and are under expert guidance. It were superfluous to dwell upon the value of these both geologically and from a mining point of view.

5. The Congress possesses the necessary powers for awarding prizes for special achievement in pure or applied geology. The Spendiarow prize, founded by Mr. Spendiarow, of St. Petersburg, in memory of his son, is awarded at each Congress for the most important work accomplished by an individual since the preceding Congress.

Referring again to the excursions, it may be that they will be conducted for the benefit of members of the Congress who are geologists, mining engineers, geographers, or are otherwise engaged in the study or application of some branch of geology. If possible, arrangements will be made to enable the wives of members to participate in the excursions. To reserve accommodation, application must be made in writing on the form provided, and must also be accompanied by the specified deposit. No deposit will be returned after the fifteenth day of June, 1913.

The International Geological Congress will hold its twelfth meeting in Toronto from the 7th to the 16th of August, 1913. Headquarters will be at the University of Toronto. Both before and after the Toronto sessions there are numerous excursions covering practically all Canadian territory available by railway and of interest to excursionists.

[Editor's Note.—The full schedule will be published in a forthcoming issue of the Canadian Mining Journal.]

The topics to be discussed at the sessions of the Congress are varied. First in importance is the subject of the coal resources of the world. Following the example of the Eleventh Congress, there is to be published (it is hoped in time for the Toronto sessions) a large compilation covering the world's known coal resources, and discussion will crystallize round this volume. Other subjects, such as differentiation in igneous magmas, the influence of depth on the character of metalliferous deposits, the origin of pre-Cambrian sedimentaries, and many other questions will be debated. As many of the most eminent authorities in the world will join in these discussions, there is no hyperbole in saying that history will be made.

. . . . . .

The International Geological Congress has accomplished the magnificent task of compiling geological maps of the continent of Europe. In this work it has received the hearty co-operation of the various international governments and of many emminent men of science. The published volumes on the Iron Ore Resources of the World, and the forthcoming volumes on the Coal Resources of the World, will be lasting monuments to the fame of the Congress. To quote an apt sentence from an official circular: "The Congress serves in a sense as an international clearing house for geology." It consolidates and clarifies the results of current investigation, and raises the whole science to a better and loftier plane.

Other sessions have been held under the direct patronage of the King or President of the country where the gatherings took place. The Canadian Congress will be under the Presidency of the Governor-General, His Royal Highness the Duke of Connaught.

No one can measure the good that will accrue to Canada from the meetings and excursions of the Congress. Apart from the direct advertisement thus given our country, there will inevitably be given a strong impetus to education, research, exploration, and actual mining development.

[Editor's Note.—All the civilized countries of the world have sent in contributions with maps on their coal resources, and these with about one hundred pages of condensation and correlation will make up the three volumes dealing with this important subject. There will be two quarto volumes of letterpress and a large volume of maps, published by Morang & Company, of Toronto, which is a guarantee that it will be well done. The volumes will be ready for distribution when the Congress meets, and we propose in a subsequent issue to give a detailed account of the countries contributing. An immense amount of information for the first time will be made public in thes volumes. The system of classification which was adopted by the Coal Resources Committee met with universal satisfaction, not a single objection having been raised to it.]

# THE HAILWOOD GAS-CAP OBSERVATION MACHINE*

By E. A. Hailwood.

The Hailwood gas-cap observation machine, which calls for no expert knowledge on the part of the operator, and requires no motor or similar auxiliary and expensive device, is made in two types, i.e., the drum-type and the gallery type.

In attempts at standardizing the apparatus, difficulty was experienced in arriving at a suitable method of fixing a constant pressure of the ingoing gas. Owing to the comparatively small quantities required to make mixtures of even up to 5 per cent., it was found to be practically impossible to properly control the pressure on the ordinary gas mains with valves, water-gauges, ordinary gas- pressure regulators and variable regulating valves. The regulation of ordinary gas-pressure regulators, to correspond with certain readings of the water-gauge, did not prove sensitive enough, because, in the first machine, on changing the nipples, the bore of which varied to represent varying percentages, it was found that the mixture did not always correspond, the results also varying from day to day. A reduction in the bore of the nipple apparently caused the gas to rush through at a quicker and uncertain velocity; possible the reduction of bore caused a back resistance, which created an accumulation of gas under pressure between the nipple and the water-gauge or ordinary pressure regulator, this accumulated pressure evidently causing the increased velocity, which upset the calculations of desired variations in the gas mixture for certain variations in the bore of the nipple. For most general purposes such a variation would have been of no moment, but for gas-cap observation, in which a variation of 0.5 per cent. is important, this uncertainty was a serious drawback, especially when the constant fluctuation in pressure of town gas is also borne in mind. In the gallery-type the difficulty has been overcome by allowing all surplus and back-pressure gas to escape through a water or glycerine seal, the supply of gas, in consequence, being received from a source always maintained at one definite pressure, and the mixture therefore now responds to the several variations in the bore of the regulating valve, which represents the various percentages of gas.

The very small quantity of gas consumed in these machines allows of their use in an ordinary room, in contrast to other apparatus, especially of the motor type, which require such a comparatively large quantity of gas that the outlet must be connected to the outside atmosphere, when, if the wind be blowing in a certai ndirection, the amount of air blown back into the apparatus, or the resistance to the free exit of the gas-mixture, may possibly dilute or upset the percentage.

The lamps are not open to the ordinary atmosphere, and should therefore truly indicate the actual mixture in which they stand. In a test with a machine open towards the bottom, a distinct diminution in the cap was observed when the gas-mixture was driven at the lamp in a vertically descending direction, as compared with the cap obtained when the same gas-mixture was horizontally received. The gas-mixture escape was at the bottom of the chamber in the first set of tests, and at the opposite side in the second. The difference was particularly marked in the higher percentages, of say 5 per cent. upwards. This would seem to point to the possibility of inaccurate readings

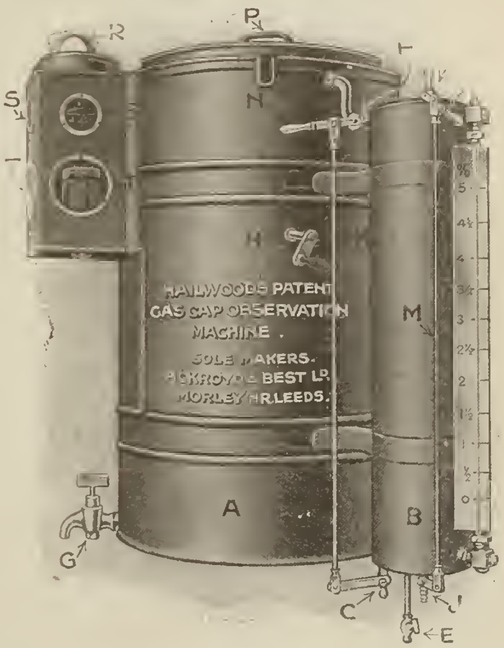


Fig. 1.

in the past, as if when sending gas downwardly at a lamp it requires more than 7 per cent. to give the "7 per cent. standard reading of the gauze being full of flame," it would seem to follow that, as the starting percentage is wrong, subsequent percentages obtained by the insertion of nipples of varying bore may also be wrong to a corresponding degree. In the gallery-type the great length of the gallery, the comparatively low velocity of the mixture, and the several mixing-plates, ensure a uniform blending of the mixture, which, the writer contends, is obviously better

*Abstract of paper read before the Institution of Mining Engineers.

than the method in which the gas is driven down at a high velocity on to the lamp. In the latter method, probably the great velocity, and the large open mouth of the chamber, admit of eddy currents of varying degree of dilution forming, and, therefore, the percentage of gas in different parts of the chamber may vary, and lamps of different heights may have their flames at other than the position at which such apparatus was calibrated.

In both types the lamp is completely enclosed in the gas-mixture, in the former the carbonic acid being absorbed as described, while in the latter the products of combustion from the lamp flame pass away through the chimney of the apparatus. Owing to the smallness of the usual testing-flame, the consumption of oxygen is comparatively low, and in any case the writer would suggest that his system apparently is better than one in which any part of the lamp is open to an atmosphere other than the gas-mixture, such, for instance, as the device in which the gas-mixture is sent into the middle portion of the lamp, apertures being left open at the top of the lamp for the escape of the consumed gases. In this case there is a great possibility of ordinary air, owing to its relatively higher specific gravity, de-

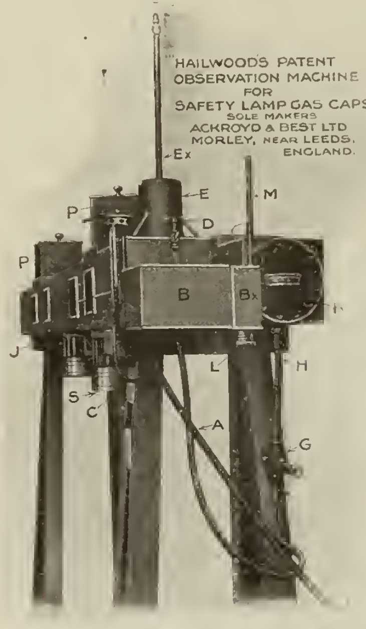

Fig 2.

scending through such apertures and diluting the lighter gas-mixture as it enters the lamp. The writer is of opinion that any lamp open to atmosphere, or any observation apparatus open to atmosphere, in the vicinity of the lamp, is subject to eddy currents or dilutions, generally to an unknown extent.

Both the drum and the gallery types are calibrated in such a manner that when using town gas allowance is made for the non-combustible gases generally present in such.

By experiment the writer hopes to show that, so far as the visible effect on the flame is concerned, the gas-caps of equal percentages of town gas and air, and of fire-damp and air, are to all intents and purposes identical, and that whereas town gas usually contains some gases of high illuminating power, these, so far as gas-caps are concerned, are nullified or balanced by the lower illuminating power of the comparatively high percentage of hydrogen usually present, as compared with fire-damp. This, the writer thinks, proves the error of recent arguments that it was wrong to employ town gas as a substitute for fire-damp in flame gas-cap testing by firemen. Town gas might give different results to fire-damp when platinum detectors, as in the Holmes Ralph gas-detecting portable electric lamp,* are employed, but there seems to be practically no difference in the effect on a flame-lamp.

The following are descriptions of the two types of apparatus:

### The Drum-Type.

This type (Fig. 1) consists of a large drum, A, to which is attached a measuring drum, B, and an observation chamber for holding the lamp, which stands in a water-ring seal, so arranged that the pricker can be operated from the outside.

The machine is adapted for use with either ordinary town gas or with cylinders of compressed gas, and will, it is thought, prove of great utility at collieries which are not supplied with the former.

The mode of operation is as follows:

Tap C is opened and the measuring chamber, B, filled with water. The gas tap, D, being now opened, the water is allowed to escape from the measuring chamber, B, by means of the tap, J, gas entering and taking its place, water to the level of the zero mark being left to form a seal. The taps D and J are coupled together by a rod, M, to ensure their working in unison. The gas tap, D, should then be closed and tap E momentarily opened to allow any surplus gas in the measuring chamber, B, over and above atmospheric pressure, to escape.

Tap F in a pipe communicating between the measuring chamber, B, and the drum, A, is now opened, after which water is again allowed to enter the measururing drum, B, through the tap, C, until the level upon the water-gauge indicates that the desired quantity of gas has passed into the drum, A, which is normally full of air. The taps C and F are coupled together by a rod, K, to ensure their working in unison. Each division upon the water-gauge represents ½ per cent., so that to pass 1 per cent. of gas into the drum it is only necessary to allow sufficient water to enter the measuring drum, B, to cover two divisions of the scale; 1½ per cent., three divisions; 2 per cent., four divisions; and so on. To allow an equivalent quantity of air to escape from the drum, A, tap G is opened whilst gas is being driven in, and a handle, H, connected with a large mixer, is rotated from time to time to well blend the mixture.

To absorb any carbonic acid given off by the lamp a tray of caustic-soda or ordinary ground-lime may be placed in the drum, A, the lid, P, of which, resting in a water-ring seal, is detachable.

With this machine it is a simple matter to rapidly change from small percentages up to 5 per cent., at which the gas-cap reaches towards the top of the lamp gauze. If more than a 5 per cent. mixture is desired, it can readily be obtained by recharging the measuring chamber, B, with gas, and operating as already described.

In the observation chamber the lamp is accessible, and quite close to the eye of the observer. At very low percentages the gas-cap remains steady for 15 to 20 minutes, and at high percentages for a few minutes. An average of not more than 5 minutes for observations of each percentage is recommended, but if a longer period be desired larger chambers are made for this purpose.

*"The Holmes-Ralph Gas-detecting Portable Electric Lamp," by Geo. J. Ralph, Trans. Inst. M.E., 1911, vol. xlii, page 201.

Before using the apparatus care should be taken that the seals to the lid of the large drum and the lid of the lamp chamber are filled with water, as also the seal in which the lamp stands. The lamp seal may be filled through an aperture in the side of the observation chamber, but care should be taken to replace the screwed plug.

### The Gallery-Type.

In the gallery-type (Figs. 2 and 3) the fundamental function lies in the velocity created by a gas-flame in the chimney of the apparatus.

The apparatus takes the form of what might be called a horseshoe gallery, J, about 5 feet 9 inches in length from end to end, the front portion (one side of the horse-shoe) being arranged to receive a lamp or lamps immediately in the rear of a glass observation window or windows. The lamp or lamps may be of any usual pattern or size, and are placed under covers, P, the lower end of which rests in a water-ring seat. The pipe, A, carries town gas to an accumulation box, B, to one end of which in connected a water-gauge, N, by the pipe, C. A tube, D, provided with a cock, is also carried from the accumulation box to the chimney, E, terminating in a gas-jet pipe, Ex. A regulator-box, Bx, is attached to the side of the accumulator-box, B, a pipe from the top part of the latter passing down to the bottom of the former through a glycerine regulating cup, L. The regulator box, Bx, is provided with an overflow pipe, M, at the upper end of which the overflow gas may be ignited. A tube, F, conveys the gas at a regulated constant pressure, throgh a measuring-valve, G, and a tube, H, to the extremity of the rear portion of the gallery, which is also provided with regulatable air-supply holes, K. At intervals along the gallery gauze mixing plates are arranged.

To operate, town gas is allowed to enter the accumulator-box, B, through the pipe, A, the glycerine regulating cup, L, being screwed up or down until the water-gauge reads at the correct figure, this being dependent upon the size of the apparatus supplied; in one size the water-gauge reads at ½-inch difference of level. The measuring-valve, G, is now opened, the area of the valve port-hole exposed fixing the percentage of gas passing into the apparatus, a pointer on the valve indicating the various percentages, such as, say, 1½ per cent., 2 per cent., and so on, rising in ½ per cent. Gas-jet, Ex, in the chimney, E, is then ignited, thereby creating a natural draught in the gallery, which draws in the gas at a uniform velocity, through the pipe H, and air through the supply-holes, K. The mixture is well blended as it passes along the gallery by gauze mixture-baffles, and of course passes through the lamps standing in the gallery, before reaching the chimney, E.

With this apparatus, by the simple operation of measuring valve, G, it is possible to very quickly change the percentage from zero to the explosive point, and vice versa, and to check the skill of the student in reading caps.

The lamp-covers, P, which rest in water-ring seals, act as safety-valves in the event of an explosive mixture being ignited, and other similar, though smaller, covers are provided in the rear portion of the gallery as additional reliefs. Tubes can, if desired, be provided for the purpose of drawing samples from the gallery, in order to check and prove percentages.

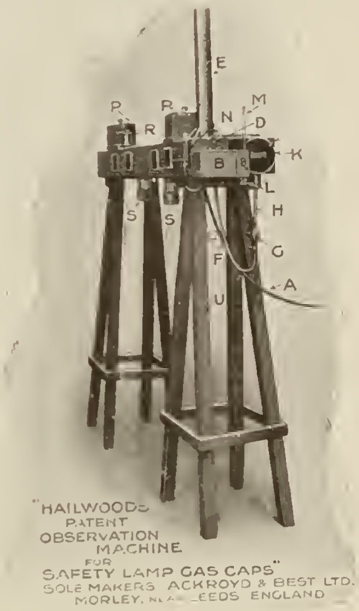

Fig. 3.

Amongst the advantages claimed for the gallery-type are the steady velocity of the mixture along the gallery, which conforms more to the conditions in an actual mine; the mixture arrives at the lamps in a thoroughly blended condition; and the lamps being completely enclosed are not so subject to eddy currents of gas, the caps therefore truly indicating the percentage of the mixture passing.

It is thought that an apparatus provided with a chimney, as in this, and so pulling the mixture past and through the lamps, gives an infinitely superior result to when the current is driven at the lamps. In the latter method the gas seems to advance in layers, waves or eddies, and when it reaches the lamp may not be thoroughly blended; therefore, lamps placed in different positions in the testing-chamber of such a machine may give varying unknown percentages, which do not correspond with the indicator.

Care should be taken to see that all the water ring seals are full of water or glycerine, and if rubber pipes are used to convey the gas that such hang free of kinks.

Fig. 2 illustrates the principal end of the apparatus, with the chimney, E, removed so as to expose the gas-jet pipe, Ex, while Fig. 3 shows the apparatus conveniently placed on trestles U.

# MINING IN BRITISH COLUMBIA

By E. Jacobs, Victoria, B.C.

Having been requested to prepare some notes on Mining in British Columbia for use as general information on an occasion when progress in the Province was to be reviewed, I supplied the following. It appears to me probable they will be of sufficient interest to warrant their being printed in The Canadian Mining Journal, so I submit them:

### Notes on Districts.

Taking the various mining districts of British Columbia in the order used in publications of the Provincial Department of Mines, progress is noted as follows:

**Cariboo.**—Mr. John Hopp and the Quesnelle Hydraulic Gold Mining Co., are both equipped for a big recovery of placer gold whenever conditions admit of long season's gravel washing.

**Cassiar.**—Mr. J. M. Ruffner, manager of North Columbia Gold Mining Co., estimates Atlin yield of placer gold in 1912 at $275,000 to $300,000. Official estimate placed recovery at $250,000. New discovery of gold in benches of O'Donnell River and others in creeks south of Teslin Lake. It is stated that developments on the Engineer group show much rich quartz.

**Skeena.**—Hazelton district will probably soon ship ore now that the Grand Trunk Pacific Railway is open to Hazelton. The Granby Co. claims to have between 5,000,000 and 6,000,000 tons of ore developed at its Hidden Creek mines; diamond drilling indicates much more, probably as much again. The following is an excerpt from President's circular to shareholders under date Nov. 19, 1912: "The Board has authorized the completion of a 2000-ton smelter and power plant, and the work will proceed with all possible despatch, in the hope that we may be shipping copper from this property before the close of the year 1913. The final estimates are not all in, but it is believed that the smelter and town with its buildings and equipment can be completed, the power plant installed, and the development work kept up meanwhile by a total further expenditure of $2,000,000. This means about $900,000 in excess of the cash and copper now on hand."

**East Kootenay.**—The Consolidated Co. has acquired the Sullivan mine and 14 adjoining mineral claims. Most of the new development is being pushed ahead into new ground. When the company commenced operations in the Sullivan there was very little ore developed; now there is more than one year's supply at the present rate of output of 100 tons a day. Much new machinery, plant, and building here.

Kootenay Central railway is now open from Crows Nest line to Fort Steele; construction south from Golden and north from Fort Steele is in progress. This should lead to a resumption of lode-mining in the Windermere division.

**West Kootenay.**—Ainsworth Division—The Bluebell mine was worked nearly all 1912 after a year's idleness. The Consolidated Co. is now operating in old Ainsworth camp, so the outlook is better for the camp now that capital is available for development and equipment.

Extension of C.P.R. line from Bear Lake to Whitewater has induced Rotallack & Co. to continue mining at Whitewater mines.

**Slocan.**—Contsruction of railway from Three Forks to Bear Lake is most important to eastern part of Slocan division. Lucky Jim resumed shipment of zinc ore in the autumn. Rambler-Cariboo, which has much silver-lead ore developed, erected a concentrator alongside the railway and constructed an aerial tramway from mine down to mill, and comemnced milling in December. Will now be able to get some return for its extensive development (first deep-level development of importance in district) commenced in 1904 and concontinued ever since.

Deep-level development is in progress at the Payne and Slocan Star mines. At the Surprise, near Cody, good ore is being opened after several years' of difficult development work. The Noble Five is shipping after years of non-productiveness. Near Silverton there is the most productive and promising camp in Slocan, the Standard, Van-Roi, and Hewitt mines give much prominence of permanent profitableness. Standard has lately opened important ore bodies in addition to those previously being worked. At the Van-Roi during the year there was found new and valuable ore bodies. Hewitt (Silverton Mines, Ltd.), also made valuable finds and is now putting in modern concentrating plant to include an advanced flotation method for recovery of zinc as well as other saleable contents of ore.

**Nelson.**—The British Columbia Copper Co. is developing, under option of purchase, the Eureka copper mine, and has bought outright the Queen Victoria copper mine; both are situated within a few miles of Nelson City. The Consolidated Co. has acquired a three-quarter interest in the Silver King and Dandy groups, near Nelson, and has commenced work there. These companies including Nelson district in their field of activities is one of the most important occurrences of the year connected with the mining industry there.

At Ymir. the Wilcox and Dundee are both developing encouragingly, and the Yankee Girl is being worked by a Spokane company in good financial standing.

At Salno, the Emerald lead mine is continuing productive. At Sheep Creek camp the Motherlode Company operated its new stamp mill during the latter half of the year, and the Queen had important developments in the deep of its mine, with large oreshoots opened.

**Rossland.**—An excerpt from Consolidated M. and S. Co.'s last annual report read thus: "Our Rossland mine show an increase in the amount of ore developed. with, we believe, a higher average value." The assistant general manager recently said: "The development in our Rossland mines has been very satisfactory, especially so in the lower levels where large bodies of ore of very good grade have been developed. The tonnage of developed ore is larger than it had been for some time past. and the grade is considerably better. The company has kept up its usual policy of doing very extensive development work." The manager of the Le Roi No. 2, Ltd., said: "Beside the discoveries of numerous ore bodies in the better-known veins in the upper ground, the most important development is that of an ore bdy on the 1650 (Le Roi) level. This is the deepest ore known in our ground and is of good metal content, size, and character, and augurs well for the future of this part of the property in depth. Development is in progress here."

Many changes and improvements were made at the Consolidated Co's smelting works and refinery at Trail, these making for the more expeditious and economical handling of materials, and better working conditions for the men employed in the works.

**Boundary.**—Output of ore in 1912 was in excess of 1,900,000 tons, as compared with 1,187,000 tons in 1911 and 1,654,000 tons in 1910. At the Granby mines, costs for the first six months of 1912 were at the rate of 74.4 cents a ton of ore mined (less than 75 cents). During five months, February-June inclusive, cost of smelting and converting into blister copper was $1.264. Together, cost of mining, smelting and converting was $2.008, or a small fraction more than $2 per ton of ore mined. Estimated ore in sight in Granby mines on July 1, 1912 (beginning of new fiscal year), 6,433,418 tons, or five years' supply working at full present capacity of smelting works.

**Similkameen.**—In 1912 the Hedley Gold Mining Co. crushed 70,000 tons of gold ore, recovered $762,718; made a profit of $407,505 for the year's work, and bought for $150,000 adjoining property on which a large body of ore of good grade was first found.

The British Columbia Copper Co. had more than 100 men working in and near Voigt's camp, ten miles from Princeton, practically all the year; it also employed six diamond drills. Negotiations for purchase of this property are being continued.

Railway has extended from Princeton to Coalmont, on Tulameen River.

Promising new silver-lead camp has been opened at Summit, in Tulameen district.

**Nicola Valley.**—The Nicola Valley Coal and Coke Co. found a new seam of coal and proved that its other coal deposits are extensive. Railway building is active in district.

**Lillooet.**—Developments in quartz mines are most promising. Railway building is active in district.

**Coast.**—The Britannia Mining & Smelting Co. mined 193,000 tons ore and recovered between 14,000,000 and 14,500,000 lbs. of copper. It has bought much surrounding property; is doing much underground development work; providing extensive power and transportation facilities, installing modern concentration plant, and employing 600 to 700 men. There is here every indication of the permanent establishment of an important copper-mining industry within 30 miles water distance of the City of Vancouver.

The Marble Bay mine, Texada island, is now being developed at thirteenth level, 1,160 ft. deep. It has added to its waterfront shipping facilities during the year—it now has capacity for shipping 1000 tons daily. It has put in new plant and had up to 120 men employed.

Negotiations for purchase of the big iron deposits on Texada Island are still being carried on.

**Vancouver Island.**—No metalliferous mining of importance was done in 1912. Three new coal mines are being opened—one by the Pacific Coast Coal Mines, Ltd., between South Wellington and Boat harbour; one by the Western Fuel Co. at mouth of the Nanaimo River; and one in the Comox district by the Canadian Collieries (Dunsmuir) Limited. All should be mining coal before the close of 1913. The Pacific Coast Coal Mines, Ltd., is also continuing development of Suquash a practically new mine. The Can. Colls is developing a hydro-electric power system and constructing a new railway in Comox district. It will probably put in coal briquetting plant there shortly.

**Miscellaneous.**

There is a much enlarged demand for structural materials—building stone, lime, cement, clay products, etc.

The Provincial Mineralogist gives the year's values as $4,450,000.

**Summary of Dividends Paid in 1912.**

| | | Rate per annum. |
|---|---|---|
| British Columbia Copper Co. ,Ltd. | $177,512.70 | 6% |
| Consolidated Mining and Smelting Co. | 232,208.00 | 4 |
| Hedley Gold Mining Co. | 360,000.00 | 30 |
| Le Roi No. 2, Ltd. (1s. a share on 120,000 shares) | 29,400.00 | 1 |
| Standard Silver-Lead Mining Co., Ltd. | 425,000.00 | 21¼ |
| Total for year of distributed profits | $1,224,120.70 | |
| B. C. Copper Co's dividend declared in December, but payable January 15, 1913 | 88,756.35 | |
| Granby Consolidated Co.'s profits, aproximately | 1,500,000.00 | |
| Total | $2,812,877.05 | |

The president of the Granby Co. stated at the annual meeting that the company's net profits for the first half of the year had been nearly $600,000. In the second half, the company announced that profits had been about $140,000 a month. As it was generally understood that for November and December profits were higher, it seems fair to place Granby Co.'s net earnings for the calendar year at $1,500,000. Then there were known net earnings of other companies apart from dividend distributions, so that the net profits of metalliferous mining companies for 1912 were probably $3,500,000, in addition to which one or two of the coal mining companies also made profits.

# BRITISH COLUMBIA COPPER COMPANY

By E. Jacobs, Victoria, B. C.

The British Columbia Copper Co., Ltd., had a full year of mining and smelting activity in 1912. Its operations were profitable, too, for it paid two dividends—Nos. 4 and 5—each of 15 cents a share on its 596,709 issued shares, making a total distribution for the year of $177,512.70, and in December dividend No. 6, at a similar rate, was declared payable on January 15, 1913. Including the last mentioned, the aggregate of dividends paid by the company is $615,399.88.

Exact figures for December have not been received, but including an estimate for that month, the following shows the ore receipts at the company's smeltery at Greenwood from its own mines: Mother Lode, 384,190 tons; Rawhide, 267,349 tons; Wellington Group mines (3), 11,055 tons; Emma, 4,436 tons; Queen Victoria, 1,066 tons; Lone Star and Washington (U. S.), 1,946 tons; Napoleon (U. S.), 17,214 tons; total 687,256 tons. The metals recovered from these ores were: Gold, 25,643 oz.; silver, 141,222 ozs.; copper, 11,267,681 lbs.

Some notes of the company's mining operations last year follow:

**Mother Lode Mine.**

At this mine, from which more than 2,500,000 tons of ore has been mined in all years to date, operations throughout 1912 were practically nothing but ordinary mining. For the most part this consisted of drilling in advance of breaking down pillars and benches of ore, and this drilling was kept far in advance of ore-breaking requirements, preparatory to blasting with electric-fired charges. The method followed was to drill and load from 1,500 to 2,500 holes, averaging about 12 ft. in depth, connecting them up in groups of twenty-five to a group. All were provided with electric fuses, and fired simultaneously. Each of these blasts broke down many thousands of tons of ore, in some cases enough to last for shipping over several months. The average number of men employed at the mine the year through was between 100 and 110, working six days a week for about half the year, and seven days the other half. There were not any important additions to machinery, plant, nor buildings in 1912, the existing general equipment having been sufficient for all needs. The power plant was operated chiefly by electricity—the big hoist by compressed air, and the compressor by electricity, with auxiliary steam when required.

### Other Boundary District Properties.

The Emma mine, in which the company holds a three-fourths interest, was worked only in January and February, for the power plant at this mine was badly damaged—almost destroyed—by fire on February 27th, since which date the mine has been idle.

The Wellington Group mines were worked until June, when they were closed, and nothing more was done on them afterward. The company plans to do considerable exploratory work on this property next season.

### Mines in Washington.

The company owns two mines in the neighbouring State of Washington, namely, the Lone Star and Napoleon.

The Lone Star is situated immediately south of the International Boundary, and is connected with the Canadian Pacific Railway near Boundary Falls, three miles from the company's smelting works, by an aerial tramway five and a half miles long. Notwithstanding that this tramway crosses three mountain summits, it has been operated successfully from the time a commencement was made to convey ore over it.

The Lone Star was worked only during a part of the year. Owing to its high silica content it was eventually deemed inadvisable to endeavour to smelt the ore from this mine with that from the company's other mines. For some time past concentration tests have been carried out with the object of determining how best to eliminate the excess of silica. The ore presents somewhat unusual resistance to concentration, but notwithstanding this, the problem is now in a fair way toward being successfully solved. There is in this mine a large quantity of ore available, so the results of endeavors to make it suitable for smelting will have an important bearing upon the question of ore supply for the company's smelting works. In value the general tenor of the ore is higher than that of the average Boundary ores.

The Napoleon mine has worked practically all the year. The sulphide ore was sent to the smelting works at Greenwood, while the oxide ore was milled at the company's concentrating mill situated near the mine. The sulphide ore from the Napoleon is used at the smelting works, on account of its sulphur content, to regulate the grade of the copper matte. It is not, however, a barren flux, for it contains copper, gold, and silver in considerable quantity.

### Operations in Kootenay District, B.C.

The company's mining operations in Kootenay district are under the general charge of Mr. H. Johns, superintendent in Kootenay.

The first property the company took under bond was the L. H. group, situated about six miles southeast of Silverton, Slocan Lake. Development work was commenced here in the latter part of 1911 and continued through the winter until February, 1912, when the snow was too deep to allow of communications being kept open, and conditions generally were unfavorable for work, so nothing was done for four or five months. In July exploratory work was resumed with eleven men employed, and to date results have been, on the whole, fairly satisfactory. Two levels are being opened, these being about 90 ft. apart in vertical depth. The ore has a very siliceous gangue and contains little economic mineral other than gold, which is in iron and associated arsenical sulphide. Concentration before smelting will be necessary, to get rid of the excess of silicia. The upper workings are at an altitude of about 5,600 feet above sea-level and approximately 3,840 feet above Slocan Lake. The Provincial Government granted an appropriation towards the cost of building a wagon road a distance of, roughly, three and three-quarter miles, to connect with an existing wagon road from Silverton southward, and this work has been finished to within 2,000 feet of the mine, when snow fell and compelled completion to be deferred until next season.

The Eureka, which was bonded at the end of last July, is situated about nine miles from the city of Nelson, and ever since then up to 25 men have been employed at this mine, doing development work. The ore contains copper, gold and silver, in a gangue of altered limestone. Buildings have been erected for the accommodation of the men, and a route surveyed for an aerial tramway from a proposed new tunnel site to the Canadian Pacific Railway across Kootenay River, a distance of about 12,000 feet. The construction of the tramway, however, will not be commenced before next spring.

The Queen Victoria group, near Beasley siding, on the north side of Kootenay River and about nine miles west of Nelson, was acquired by purchase at the beginning of November. This mine is fully equipped for operation, having all requisite mine buildings, water supply, electric-driven compressor, and an aerial tramway down to the Canadian Pacific Railway below. The development work done by previous operators consist chiefly of three adits from which raises have been made to the ore, which is an altered lime, similar in general character to the prevailing copper ore of Boundary District. About a dozen men were set to work in November, and the number increased as matters became favorable for employment of a larger number. Arrangements have been made for transportation of the ore over the Canadian Pacific Railway to the company's smeltery at Greenwood. It was intended to ship from 500 to 1,000 tons a week; the quantity is dependent upon the capacity of the aerial tramway, which was not known when these particulars were obtained.

### Voigt's Camp, Similkameen.

Two groups of mineral claims, situated about ten miles south of Princeton, east of Similkameen River, and along Wolf Creek, were being developed by the company under option of purchase. The larger of these, known as Voigt's group, comprises 55 claims and fractions; the smaller, known to the company's officials as the "upper camp," includes the Ada B group and several individual claims, eight in all. Development work was commenced by the company on these properties in October, 1911, and was vigorously carried on until late in 1912.

A great deal of exploratory hand work was done on the Voigt group, and much diamond-drilling as well. Commencing with 16 men and two diamond drills, op-

**2nd LEVEL CONIAGAS MINE—SHOWING PILLARS**

(NOTE THREAD OF LIGHT FROM MOVING CANDLE ON LEFT.)

erations were enlarged until six drills were in use and upwards of 60 men employed. In addition to doing about 1,500 feet of underground hand work—cross-cutting, drifting and shaft-sinking—and many thousand feet of diamond drilling, several thousand feet of surface trenching was done. As yet no information is available for publication relative to results of this work, for at the time of writing no statement had been made public as to whether or not the company will make a comparatively large payment on the bond that was due in December.. Judging by the statements of those who have for years been engaged in prospecting on the Voight property, there are large showings of ore on various parts of this big group of claims, and it is hoped that the company will have found the ore deposit big enough and of sufficiently good average grade to warrant it in taking up its bond.

The "upper camp" adjoins the Voigt group on the south The underground development work done consists of some 700 feet of shaft-sinking, cross-cutting, and drifting, while fully 1,500 feet of diamond-drilling has also been done. On the surface, several thousand feet of trenching has been part of the exploratory work. There were in November two diamond drills being used and the working force included in all, about 30 men.

The ore met with in this camp varies as a whole, from heavy hematite containing copper and iron sulphides with gold and silver, which ore is base, to ore containing a high percentage of silica with similar economic minerals. The geology of the camp has not yet been thoroughly worked out, but as a rule the tendency of mineralization is along fracture zones extending in a general direction from the southwest toward the northeast, the surface mineralization being extensive. Details concerning the ore bodies, however, are not yet made known.

The company erected in the lower camp numerous temporary buildings, while in the upper camp a substantial bunk and boarding house has been built. The plant put in included one 80-h.p. steam boiler connected to two 3-drill compressors, half a dozen small boilers for operating diamond drills, small hoists, etc., and pumps, piping, tram rails and cars, and all other equipment requisite for doing the work that has for months been in hand. Part of the diamond drill plant is owned by the company, and the remainder by contractors, the drilling being done by contract.

### New Dominion Copper Co.'s Mines.

The British Columbia Copper Co. holds a controlling interest in the New Dominion Copper Company, which owns several mines in Boundary district. The only one of these mines that has been operated on a large scale last year was the Rawhide, situated near Phoenix. Work was continued all the year, and much development—new adits and raises, chiefly—was done, besides which a large quantity of ore was mined and shipped to the company's smelting works at Greenwood.

Included in the new work was a branch of the lower tunnel, connecting with the ore-shipping bins. An electric haulage system was put in, to take the place of hauling with horses. The footage of development work done in 1912, including an estimate for November and December, is placed at 2,656 feet, some 2,116 feet of raises and drifts to October 31, and 540 feet estimated for the two remaining months.

# COBALT AND ADJACENT AREAS

By Willet G. Miller.*

The invitation of the editor to write a short paper on Cobalt for this review number of the Journal has been accepted not because I feel that I can add anything new to the description of the silver areas, but because I am willing to try to assist in the review. Stocktaking is valuable. A consideration of the successes and failures of the past, together with a description of present conditions, should be of service in planning for the future. While I have not the time, even had I the inclination, to attempt a systematic review, other writers in this number will doubtless have rendered it unnecessary.**

### Production and Extent of Territory.

Cobalt proper, or the area about six miles in extent in the township of Coleman, has produced approximately 154,000,000 ounces of silver since the end of 1904. When, however, it is considered that the geology of this area is similar to that of numerous other areas, in several of which either cobalt, or cobalt and silver, have been found, it may reasonably be expected that in a region approximately 5,000 square miles in extent, important discoveries will be made in localities that at present are unproductive. The success that has been met with in Casey, South Lorrain, and Gowganda will encourage more systematic and intensive work in other areas than has hitherto been performed.

Characteristic cobalt ores have been found as far south as Rabbit Lake, which lies south-east of Temagami, as far north as Wendigo Lake to the north of Casey, as far north-west as the township of Langmuir south-west of Porcupine, and as far west as Shining Tree. Surely within this region, productive areas, as yet undiscovered, will be developed!

In the earlier years of prospecting and mining at Cobalt it was the rule to look for quick returns, either from mining rich ore or in selling properties. Much territory, for instance, lying on either side of the line between Cobalt and Elk Lake, had little systematic work done on it. It contains many six-mile areas that cannot be said to be barren. The same can be said of other non-productive areas in the 5,000 square mile region.

### Structural Relations.

Whatever may be thought of its being helpful in theology, dogmatism should have small place in the natural and physical sciences. Hence, in the papers and reports I have written on Cobalt I have tried to avoid being dogmatic. I have not felt, for instance, that all is known concerning the origin of the cobalt-silver ores. Indeed, the more I see of the cobalt and certain other ore deposits, the less reason there is, it seems to me, for any person being dogmatic concerning the origin. If there is anything more complex than the origin of certain ore deposits it probably is only animated nature. We can never hope to know much concerning the interior of the earth, or even of

*Ontario Provincial Geologist. **The wording in this paragraph, and the general character of the paper, are due to the paper having been written with the object of using it as an introduction to a review number of the Journal.

that part of it two or three miles below the surface. We may dogmatize and propose attractive theories and hypotheses, but we have few facts and are almost helpless when it comes to the consideration of the effects of combination of causes that are represented by certain ore deposits. Superman may solve the riddle!

While we may not claim to know all about the origin of the ores at Cobalt, there are certain facts and inferences therefrom that are helpful at least in a utilitarian sense. We know, for instance, that in every area in which cobalt or cobalt-silver ores have been found throughout the 5,000 square mile region, the Nipissing diabase is present. Hence we can conclude that this diabase played an important part in connection with the origin of the ores. Whether, however, the impure waters that accompanied and followed the diabase intrusion and deposited their metallic contents in the cracks and fissures, giving rise to the veins, received all of their contained metals from the diabase magma, or whether some of the metals were derived from rocks through which the diabase was intruded is conjectural. Then the normal order of the deposition of the various ores in the veins is fairly well known. But too hard and fast lines should not be drawn. Moreover, because native silver in certain deposits in other parts of the world can be proved to be of secondary origin, resulting from the decomposition of ores or minerals, it should not be said without reservation that all the native silver at Cobalt is of such secondary origin. From observation on a few veins it should not be said that physical-chemical influence of the country rock played an important part in ore deposition. Nor should it be said, of areas in which Nipissing diabase is present or has been removed by erosion, that veins will not be found in certain rocks. In the notes accompanying the first map published of the Cobalt area prospectors were advised to give special attention to the conglomerate. This did not mean that no veins were likely to be found in the diabase or Keewatin, but that veins were likely to be much more numerous in the conglomerate. Prospecting and mining during the last eight years have proved this early advice to have been sound, over eighty per cent. of the production having come from the conglomerate.

### Geological History.

The "great stone book", the crust of the earth, especially if a restricted area or district on the surface of the globe is considered, has been compared to a volume in which pages and even chapters are missing. It is well, we may repeat, not to be dogmatic and affirm that the complete geological history of any area is known. What author has been able to write a history of a people that is complete? Characteristics of an age, or of a people, may have been preserved in the writings of certain contemporary authors that may afford the later historian material for a true account of a limited period. But the data on other ages or periods are incomplete. Similarly in working out geological history, data are sometimes discovered that make the history of restricted periods clear and distinct. An unconformity or a good contact may throw as much light on the physical history of a period as does, for instance, Pepys' diary on a period of British history. But such contacts or diaries or other records are not always available, and the complete history cannot be written.

At Cobalt and in the surrounding region data are found that make clear part of the complex geological

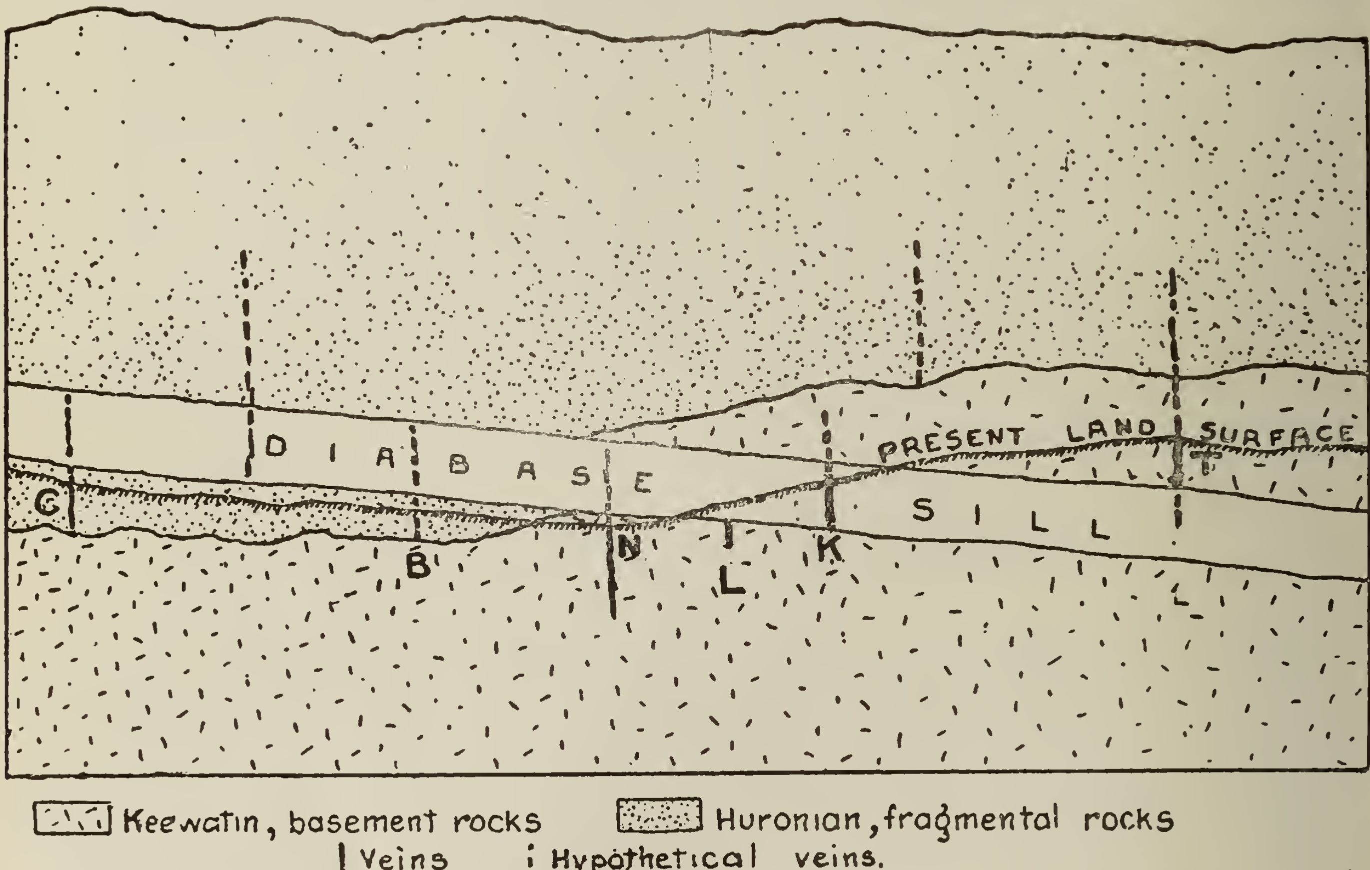

Fig. 1.
CROSS-SECTION, IDEAL RESTORATION OF ROCKS AND VIEWS AT COBALT.

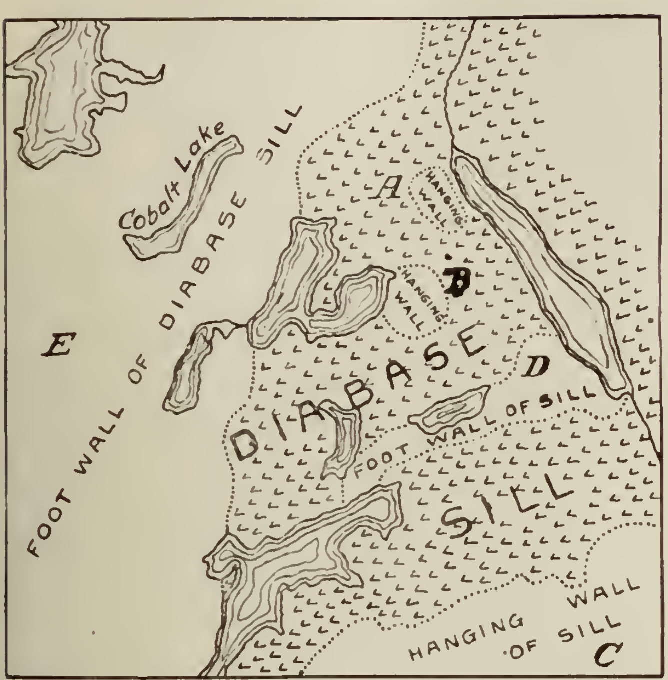

Fig. 2.

history. While a complete history of the pre-Cambrian period, to which the rocks of Cobalt belong, may never be written, enough is known to be of value for economic purposes.

In the productive Cobalt area there are three great groups of rocks, each representing an important epoch in the history of the region, that are of interest from the miner's point of view. These are from the youngest to the oldest: (1) The Nipissing diabase; (2) Cobalt conglomerate and other fragmental rocks, and (3) the Keewatin complex of essentially volcanic rocks, with a minor quantity of sedimentary material.

The accompanying generalized cross-section of the Cobalt area shows the relationship of these three groups of rocks, and characteristic modes of occurrence of the veins, (Fig. 1).

The Cobalt conglomerate and associated fragmental material are the erosion products from the Keewatin and other early series of rocks of the district. The Nipissing diabase has intruded both the Keewatin and Cobalt series. It is believed that the cracks and fissures now occupied by the cobalt silver veins were formed on the cooling and contraction of the diabase. The vein minerals or ores are believed to have been deposited, as already said, from the impure waters that accompanied or followed the diabase intrusion. The parts played respectively by meteoric and what are called magmatic waters are conjectural.

The diabase, as is well known, is in the form of a great, almost horizontal sheet, or sill. Its upper wall, consisting of rocks both of the Cobalt series and of the Keewatin, has now for the most part, in the productive area at Cobalt proper, been removed. (Fig. 2). The veins in the conglomerate are in the foot wall of the sill. There are some veins in the Keewatin foot wall (Fig. 1), and in the sill itself, while two or three are in the Keewatin of the remnant of the upper or hanging wall.

## Faults.

As in many other mineral areas, faults are important features in the Cobalt area. The one which passes through the workings of La Rose mine south-west through Cobalt Lake, and the McKinley-Darragh mine is the best known, the mine workings along and on either side of it having afforded facilities for study. Fig. 3, from a cross-section by Mr. Cyril W. Knight, shows the structure at LaRose mine. Faults such as this have brought about the preservation of veins, or

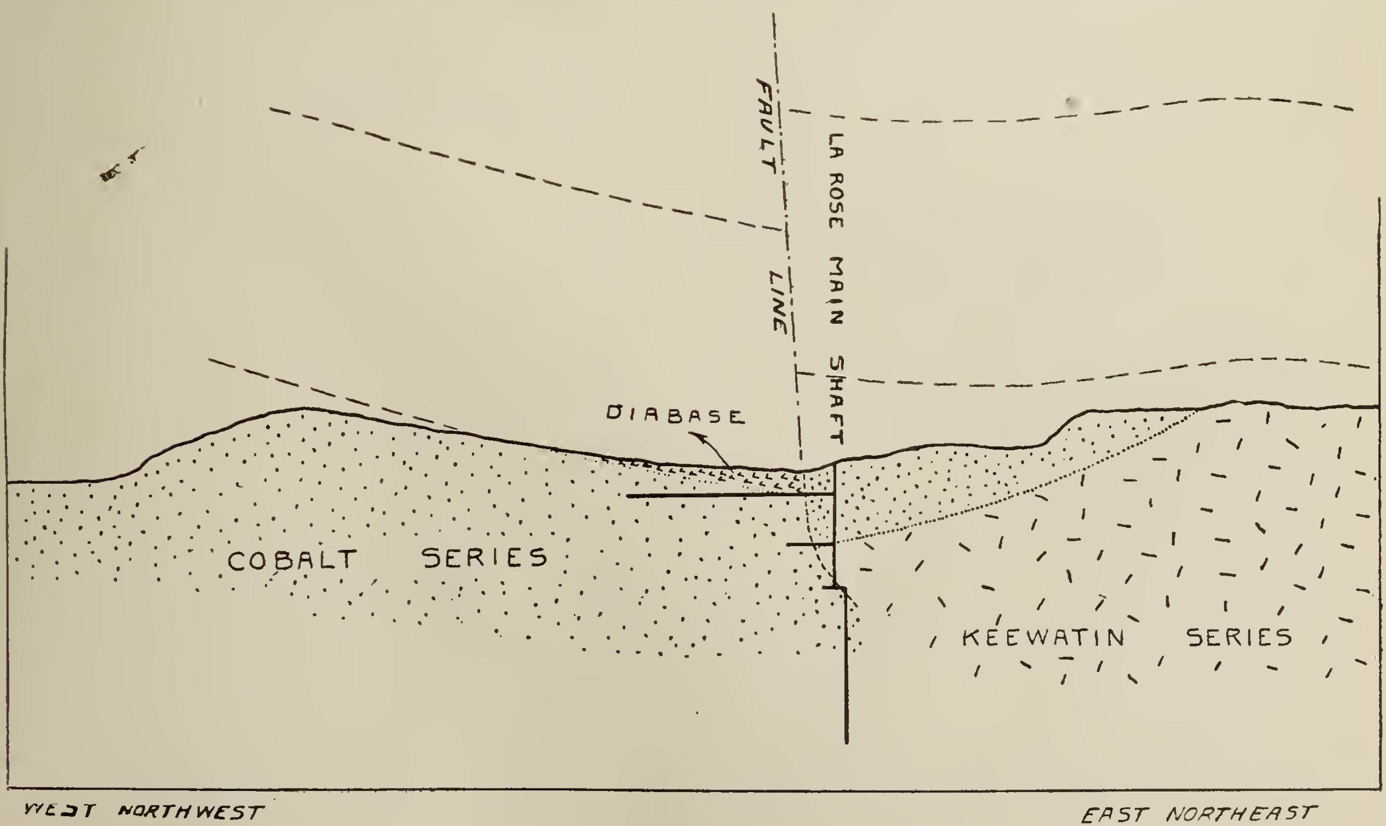

Fig. 3.

parts of veins, that otherwise would have been removed by erosion. It is probable, as I have said in another paper, that a great fault extending through Lake Temiskaming accounts for the absence of productive silver veins on the east side of the lake.

Owing to the economic importance of faults at Cobalt, careful search for similar structures, in other mineral areas of Northern Ontario, should be made. While, for instance, certain gold deposits that have been worked in years past in Ontario have been found to have no great depth, it is possible that in other areas, owing to faulting, parts of veins have been carried down and preserved from erosion, thus affording much larger workable deposits.

# PERSONAL AND GENERAL

Mr. R. J. Flaherty has returned to Toronto from Port Arthur.

Mr. J. B. Tyrrell returned from London last week. During his visit to England he examined several mines in Cornwall and elsewhere.

Mr. W. E. Segsworth was in Toronto on the 22nd and 23rd ultimo.

Messrs. W. F. Stanley & Co., Ltd., manufacturers of surveying and mathematical instruments, have taken new office accommodation at 286 High Holborn, London, Eng. They still retain the old premises at 4-5 Great Turnstile.

Mr. Robert Bryce is in Cobalt.

Mr. Geo. F. McNaughton, late manager of the Trethewey mine, Cobalt, is in Nova Scotia.

Mr. G. G. S. Lindsey spoke before the Toronto Branch of the C. M. I. on the 18th of January, an account of his speech will be found on another page.

Mr. Melbourne Bailey, manager of Mr. John Hopp's several hydraulic placer-gold mines in Cariboo district, B.C., is spending the winter at his home in Tacoma, Washington.

Mr. Wm. Blakemore, of Victoria, B.C., in the course of evidence he recently gave at a sitting of the British Columbia Labour Commission, after speaking strongly in favour of Trades Unionism, expressed the opinion that ther was little or no cause for the existing strike of Union coal miners at the mines of the Canadian Collieries (Dunsmuir). Limited, Vancouver Island.

Mr. S. G. Blaylock, of Trail, B.C., assistant general manager, has been one of the chief spokesmen for the mine owners of Kootenay before the Board of Investigation and Conciliation appointed in connection with the demand of metalliferous miners for an advance in wages at mines in that district.

Mr. J. W. Bryant, formerly chief mining engineer for the Tyee Copper Co., Ltd., when that company's mining activities were important in the Pacific coast districts of British Columbia and Alaska, recently contributed to The Mining Magazine, London, an article on "A New Copper District," in which information is given concerning Rainy Hollow district, in the extreme north-western part of British Columbia.

Mr. C. Victor Brennan (B.Sc., McGill, 1908), of Bingham, Utah, chief mining engineer for the Utah Consolidated Mining Co., on January 7 married, at Vancouver, B.C., Miss Alice Graeme McMynn, daughter of Mr. Wm. Graham McMynn, for years Gold Commissioner at Greenwood, B.C. Mr. and Mrs. Brennan will have their home at Bingham.

Following Mr. Herbert Carmichael's voluntary retirement from the positon of Provincial Assayer for British Columbia, Mr. Wm. Fleet Robertson, Provincial Mineralogist, has added the direct charge of the Provincial Assay Office to his other duties. The Assistant Assayer, Mr. D. E. Whitaker, will continue to give the whole of his time and attention to the assaying and analytical work of the office.

Mr. Kenneth B. Carruthers (B.Sc., McGill, 1908) is in charge of the Molly Gibson silver-lead mine, in Nelson mining divison, British Columbia, for the Consolidated Mining and Smelting Company of Canada, Ltd.

Mr. A. F. Eastman, manger of the mining department of the Tacoma Steel Co., which owns the Marble Bay copper-gold mine at Van Anda, Texada Island, B.C.; was taken seriously ill at the mine early in December. Later he was removed to his home at Tacoma, Puget Sound, Washington. After about five weeks' illness, he is convalescent.

Mr. Thos. Gough, manager of the Kootenay Gold Mines, Ltd., operating the Granite-Poorman gold mines and 20-stamp mill near Nelson, B.C., has been in Victoria on a short business visit.

Mr. Alexander Grant, for a number of years manger of the Marble Bay mine. Texada Island, B.C., both when it was owned by Messrs. Christie and Palmer, of Toronto, and after its sale to the Tacoma Steel Co., is spending the winter at San Diego, California.

A Boundary district newspaper states that Mr. E. Hibbert, superintendent of mines for the British Columbia Copper Co., is about to leave British Columbia to take charge of a mine near Sudbury, Ontario.

Mr. Robert R. Hedley has during recent months been active in promoting the interests of the Chamber of Mines, of Vancouver, B.C., of which institution he is chairman.

Mr. John Kirkup, for years Gold Commissioner for the Trail Creek mining division, with headquarters at Rossland, B.C., has been transferred to Alberni, Vancouver Island, the Provincial Government having acceded to his wish that he be given an appointment on the Coast. He is now Government Agent at Alberni.

Mr. Andrew G. Larson has returned to Vancouver, B.C., from a trip to Colorado and Montana.

Mr. Thomas Kiddie is now resident at West Alhambra, California, the state of his wife's health necessitating a change from the colder winter climate of British Columbia.

Mr. J. W. D. Moodie, vice-president and general manager of the Britannia Mining and Smelting Co., has returned from a trip to New York and other eastern parts, and is now continuing the active direction of the important developments underground, and additons to power, transportation, and ore-concentration facilities in connection with the Britannia copper mine. Betw[illegible] 600 and 700 men are employed by the company, which in 1912 increased its output of ore by nearly 100 per cent. (to 193,000 tons) as compared with its 1911 output.

# MINING INVESTMENTS

(Written by a Mining Accountant.)

Preliminary.

What are the prospects as regards the payment of a fair rate of interest and the ultimate return of capital, and what are the risks? are the two vital questions which should be satisfactorily answered before entering into any mining investment.

Unfortunately, the average investor does not possess the necessary knowledge of mining or the experience in mining investments to enable him to size up or review all the demerits usually so much in evidence with this, the most hazardous of all investments; and, moreover, except in cases where the mine has been sufficiently developed, even a mining engineer would not be justified in arriving at any definite conclusion regarding the possibilities ahead of the mine.

That it is possible, however, to draw a line of demarcation between what might be termed "a fairly sound investment with reasonable prospects of success," or "a rank gamble," cannot be denied; otherwise this article would not have been written in the best interests of those who, as a result of inexperience, are apt to invest their money where the prospects of the return of capital, let alone the payment of a fair rate of interest, appear anything but favourable when denuded of the glowing reports and misrepresentations which are sometimes made in good faith, but more often as a lever for unscupulous promotions.

Investments in mining stocks at par or before the mine has reached the producing stage, while offering the chance of realizing larger profits, must, for obvious reasons, be more or less of a gamble, but in cases where the mine has been reported on by a reliable engineer and systematic sampling of the surface showings reveals a continuity of payable values over an appreciable length and width, and the indications are such as to justify expert contention that the pay shoot will not diminish in legth, width, and value at depth, the acquirement of an interest in the mine can justly be considered a fairly sound investment, if it has not been over-capitalized, or, in other words, the surface indications or showings will obtain at depth, it appears evident that a large enough tonnage can be mined and treated to show a return of 20 per cent. per annum on the original capital.

If, on the other hand, however, the mine has not been sufficiently developed to justify a definite expression of opinion by a reliable engineer as regards its possibilities as a dividend earner, then the mine is still in the prospecting stage and intending investors would do well not to participate in any floatation in connection therewith, unless they are looking for the very worst kind of a gamble where the chances as evidenced by the formidable array of "wild cats" are less than those on the race course, and that, even to those who know as much about a horse as a cow does about a side pocket.

Apart from the necessary assurance on these salient points, intending investors should also satisfy themselves that the flotation involves men of high standing, who, as promoters, consulting engineers, and directors, cannot afford to risk their reputation by statements which cannot be theoretically or practically demonstrated, that the concern has not been over-capitalized, and that the working capital is sufficient to develop and bring the mine through to the producing stage, and does not indicate that either the purchase price is considerably in excess of the actual value of the property, or that the promoters' profits are unusually excessive.

A careful perusal of the memorandum and articles of association or by-laws, is also advisable, as the answering of such questions as: What are the directors' fees? How many shares must the directors hold to qualify? and what are their powers, etc., etc.? often expose conditions which are anything but favourable in the best interests of the shareholders.

A great deal more could be said on this very knotty question of sizing up the merits or demerits of mining propositions in their nifancy. This, however, when dealing with the geological conditions, favourable or otherwise, to gold deposits with permanency at depth, the evils of mismanagement, and unfavourable working conditions, etc., etc., would be unintelligible except to those having the necessary technical knowledge and experience. Moreover, that which has already been written is sufficient in itself to make it apparent that without instituting rigid inquiries and obtaining expert opinion as regards the possibilities ahead of the mine investors when relying solely on the statements of the promoters and stock vendors, are incurring risks, which, when brought to light, would cause even the most reskless speculator to fight shy of the venture.

It naturally follows that by only entertaining propositions where the risks are apparently reduced within reason, the opening up of the mineral resources of the country would be seriously retarded by such cautious proceedings. This, however, outside of the common loss thereby sustained by each and every member of the community, does not effect the individual, and is, therefore, beside the question, especially as the consistent turning down of everything in which the element of speculation predominates, would gradually force promoters to realize that without risking something to develop the mine to the point of establishing its position as a dividend earner, their chances of realizing the enormous profits (at present usually out of all proportion to the outlay) are as remote as those which under existing conditions, the average shareholder is expected to carry.

The foregoing deals with the acquirement of shares in any mining company at its inception, and although the risks are in proportion to the prospective gains, this, for reasons set out herein, appears the most favourable period in the life of the mine to become interested therein.

For example, let it be assumed that a company capitalized at $600,000, showed a profit of $200,000 over all charges, including plant depreciation and development redemption as a result of operations during the first year after reaching the producing stage, and that the positive ore reserves were such as to assure a similar profit for a further period of four years. Now, under the present methods this profit would be paid out in the form of a dividend representing 33 1/3 per cent. on the par value of the shares which, everything being favourable, would then rise in consequence until returning, say, 15 per cent. when maintaining this profit. This would represent a sound investment if the life of the mine and similar profits were assured for twenty years, but in view of the possibilities as regards the pay shoots not continuing at depth, etc., etc., it certainly could not be considered safe with only four years' ore in sight, to take such an extremely optimistic view. As a matter of fact, it would be somewhat risky to double the prospects as revealed by the actual ore in sight, or, in other words, figure on the profits being maintained for eight instead of four years. Even then the shares would not be worth their par value with only the return of capital and 2½ per cent. interest per annum reasonably assured.

This now brings us to the question of inflated stock values, and it does not require much figuring to show that the shares, when standing at a price returning only 15 per cent. on the annual profit of $200,000, would be more than double their actual value and that, whereas, when taking the precautions referred to herein, the investment at par offers a good fighting chance, the purchasing of shares as an investment after payment of the first dividend, is very much more of a gamble, as there is then no doubt that on such an inflated valuation the mine is very much over-capitalized on the showings, even when making very liberal speculations thereon in the manner suggested. The undeniable fact that it needs to be a very good mine, indeed, which after ten years, let alone twenty years, does not at least reveal conditions necessitating a reduction in the grade of ore milled, further supports the contention that until a healthier tone is imparted to mining as an investment by adopting methods more in keeping with sound business principals, the acquirements of stock in any mining company at its inception offers better prospects of success when taking reasonable precautions such as already suggested herein.

That such should be the case clearly shows that there is something "rotten in Denmark," and in our next issue we will attempt to demonstrate that mining, which at best can now only be considered in the light of a speculation, can be made more of an investment after the mine has reached the producing stage, by distributing the surplus over revenue expenditure (now erroneously called profit) in such a manner as to keep the shares at their true value.

(To be Continued.)

## MACHINERY NOTES

### Model New Plant of H. W. Johns Manville Co.

The completion of the new plant of the H. W. Johns-Manville Co., at Manville, N.J., marks another important chapter in the history of this concern.

Beginning with the consolidation of the H. W. Johns Manufacturing Co. and the Manville Covering Co., in 1901, the H. W. Johns-Manville Co. has grown by leaps and bounds until to-day it ranks as the largest concern in the world engaged in the manufacture of asbestos and magnesia products.

Branch houses are established in practically every city of prominence in the United States and Canada, and representatives in almost all foreign countries. Manufacturing plants are located in Brooklyn, N.Y.; Milwaukee, Wis.; West Milwaukee, Wis.; Hartford, Conn.; Nashua, N.H.; Lockport, N.Y.; Jersey City, N.J.; and an asphalt refinery at South Amboy, N.J. The company's asbestos mines at Danville, Province of Qubec, Canada, are the largest in existence, and produce the finest grade of asbestos.

The new Manville plant consists of nine buildings, which, together with their products, are classified as follows: A, textile and packing; B, rubber plant, electrical specialties and printing department; C, pipe coverings; D, paper mill; E, magnesia; F, roofing; G, mastic and waterproofing; H, roofing coatings; power plant and pump house.

These buildings represent the most advanced ideas in fireproof construction, being of brick, steel and concrete, with roofs of J-M Asbestos Roofing. They are planned not only for safety, but to afford the best operating conditions for the employes. The "daylight" form of construction which is employed throughout pemits a flood of light to enter the buildings through large triple-unit windows placed close together. Artificial illumination is provided in the form of J-M linolite lamps and Frink reflectors.

The hygienic conditions of this plant are ideal. Ventilation is furnished by means of steel ventilating sash which provide a constant supply of fresh air without causing drafts. Owing to the judicious arrangement of the macihnery, there is an entire absence of crowding and confusion which, in many factories, serve to hamper the operators in their work.

Each building has an average length of 1,000 feet, and is a separate factory in itself capable of being operated as an independent unit without relation to the other buildings in the group. The total combined floor area of all the buildings is about 1,000,000 square feet.

Power is furnished by the company's power plant which consists of the latest type of General Electric turbo generators, six Babcock & Wilcox high-pressure water-tube boilers aggregating 5,000 horse-power. All steam pipes are insulated with J-M Asbestos-Sponge Felted Covering in order to effect a maximum saving of fuel. The power and lighting cables, instead of being strung on overhead poles, as is generally the case in factory installations, are led underground through J-M Fibre Conduit, thereby eliminating cable trouble for all time.

The new plant is situated on a picturesque tract of 320 acres, divided by the Raritan River, in the town formerly known as Findern, N.J. The name has since been changed to "Manville." The company's private railroad system, comprising five miles of tracks, connects directly with the Central Railroad of New Jersey, the Lehigh Valley, and the Philadelphia & Reading Railroad, thereby insuring excellent shipping facilities.

About 3,000 men will be employed at this new plant, making a total of about 7,000 who are now employed by this company.

During the month of December the Elmore Vacuum plant at the Sulitelma mine, Norway, produced 650 tons of copper concentrates.

Danger signals for mines are being manufactured by the Stonehouse Enamelled Steel Mine Signal Co., of Denver. The signals are so designed as to attract immediate attention. The significance of the sign is perceived even by foreign labourers.

The Siemens Company, of Montreal, has received an order for a 5000 K.V.A., 3-phase, 60 cycle, 1800 r.p.m. tubo generator from the corporation of Edmonton. The generator is to be provided with the Siemens systems of axial ventilation so arranged that the hottest temperature in the machine can be measured. The Siemens Company has already supplied Edmonton with two generators and one induction motor.

**Pile Hammers.**—The McKernan-Terry Drill Co., New York, is putting on the market both heavy and light pile-hammers. To the former has recently been added a new accelerating device in form of an accelerating piston. Steam or air is conducted into the internal cylinder of the main piston through a small port in the accelerating piston, and is held against escape by a check valve. Entering on the downward stroke, it is highly compressed on the upward stroke. By this means not only is acceleration attained, but a positive cushion is provided.

# GOLD ON VANCOUVER ISLAND

In his recently-issued Memoir on South Vancouver Island, published by the Geological Survey of Canada, Mr. Charles H. Clapp, of that department, who began a geological examination in 1908 and continued it the following years, under the head of Economic Geology says that there are in southern Vancouver Island mineral deposits valuable, or possibly valuable, for gold, copper, iron, fluxes and pigment; also important structural materials including lime, and cement, clay, sand and gravel, and stone. Concerning gold, Mr. Clapp reports:

**Placer-Gold Deposits.**—Placer-gold deposits are the chief source of gold in southern Vancouver Island, and the only source which has here produced gold in paying quantity. Gold is reported from a large number of rivers and creeks on southern Vancouver Island, and "colours" can doubtless be obtained by panning in most of the streams. With two or three exceptions, the principal deposits all occur, however, in the streams which flow for a considerable part of their course over the Leech River formation. The gravels and sands near the mouth of Sombrio River have been known as a source of gold since the Spaniards explored the Pacific coast in the latter part of the eighteenth century. In the sixties the deposits in the Leech and Jordan rivers were discovered and worked the yield being estimated at between $100,000 and $200,000; and, somewhat later, coarse gold was found in the upper part of the San Juan River. For a number of years Chinamen have worked on Leech River, and one or two more extensive attempts have been made recently to obtain gold from Leech River and its north fork. At present, a partnership has been formed to work a large deposit of sand and gravel near the mouth of Sombrio River. Beside these deposits, which occur in the belt of the Leech River slates, small amounts of gold have been obtained from China Creek and Franklin River, emptying into Alberni Canal, and also from Nanaimo River.

Virtually all of the streams which occur in the belt underlain by the Leech River slates contain more or less coarse gold. With the exception of the two large valleys which occur along the northern and southern boundaries of the formation, the San Juan valley, and the valley which has been called Leech River valley (but which is occupied by several streams beside Leech River, notably Jordan River and its tributaries Bear Creek and Y Creek, and Lost River), the valleys are narrow and the grade steep. The amount of gravel in these streams is, therefore, small. It is very possible that relatively large amounts of auriferous gravel may be found on the wide, comparatively smooth, interstream areas. These interstream areas are, as a rule, drift-covered and heavily timbered, so that prospecting is carried on with considerable difficulty.

The amount of gravel, even in the Leech River valley, is not large throughout the greater part of its extent, but special conditions have existed in certain portions, which have caused its accumulation in large amounts. The conditions are not at present well understood. The largest known deposit occurs in the lower part of the valley, extending to the coast near the mouth of Sombrio River. Lost River, which occupies the western part of the Leech River valley, does not cross these gravels, but turns abruptly to the south more than a mile from the shore, and finds its way to the sea through a narrow canyon. The gravels are underlain by Tertiary conglomerate and sandstone, which are exposed at the shore and at the bend of Lost River at 320 ft. above sea-level. Near sea-level the Tertiary rocks are directly overlain by a sandy clay of indefinite thickness, but probably not more than 10 or 15 ft., which contains marine Pleistocene fossils. The overlying sand and gravel is from 300 to 500 ft. thick, and the deposit is one-quarter to one-half mile wide, and extends inland beyond the bend of Lost River, for a distance reputed to be more than two miles. On top of the gravels is a yellow garnet-bearing sand, 10 to 20 ft. thick, occurring at elevations of from 450 to 500 ft. above sea-level, although near the shore it occurs much lower, probably on account of local slips in the deposit. The sand consists largely of rounded quartz grains, and resembles a beach sand. Mr. R. S. Gallop, one of the partners who own the deposit, in a recent letter to Mr. Clapp, states that the mining engineers who have examined the deposit estimate the amount of gravel at 155,000,000 cubic yards, and th gold content at 12 cents a yard.

The orgin of the gravels is not at present clear. A large part of the gravel contains pebbles of many different rocks, and appears from its heterogeneous character to be composed of glacial detritus. It seems probable therefore, that the gravel was deposited by a large, post-Glacial river flowing westward in the Leech River valley before the recent uplift. This uplift diverted the river into its present course, that of the Lost River. The gold, if deposited under these conditions, was probably derived from a much larger quantity of glacial gravels.

A large amount of gravel occurs also in San Juan valley, but is probably low grade, as it is chiefly of glacial origin, and any gold that it contains does not appear to have been especially concentrated, except very locally.

The gold in the above-mentioned gravel deposits has doubtless been derived from the quartz veins which occur in the Leech River slates. These quartz veins, or more correctly small stringers and lenses, are very numerous, but they seldom attain any great size. The quarts of the veins is associated with a little albite, which in the sheared veins has altered to sericite. The only metallic minerals are a little pyrite or chalcopyrite, and free gold. The veins are, as far as known, very low grade, and are too small and barren to be profitably mined, and all attempts which have been made to work the veins have been unsuccessful.

The only development of the gold deposits of the Leech River belt going on at the present time is that of the large deposit of sand and gravel occurring along the west coast, near the mouth of Sombrio River. Messrs. R. S. Gallop, D. W. Hanbury, and W. H. Kirkbride have nearly finished the construction of a hydraulic plant to work these gravels. It is possible that other gravel deposits, sufficiently large to pay for the establishment of a plant, occur in other parts of the Leech River valley. As far as known these deposits are small, but the western portion of the valley has never been explored. Although the deposits of the San Juan valley are low-grade, thorough examination may reveal enough gravel to warrant the establishment of a plant designed to work large quantities of low-grade material. Thorough prospecting of the gravels on the upland between the two major valleys is also advised.

The upper parts of the Franklin River, China Creek, and Nanaimo River flow in a mountainous district formed of the Vancouver meta-volcanics, with intercalated lenses of limestone, both of which have been invaded by large granitic batholiths. Considerable mineralization has taken place near the contracts, and it is probable that the small amount of gold in the above-mentioned streams has been derived from mineral deposits of the character. As far as seen, the gravel deposits of these streams, which are likely to be gold-bearing, are very bouldery and restricted in amount.

Along the west coast of Vancouver Island, except where fringed by the Tertiary deposits, black sands which contain gold occur in the beaches. The gold, however, is quite flaky and would probably be saved only with considerable difficulty, as has proved to be the case farther north along this coast. The actual amount of black sand in the beaches of southern Vancouver Island does not appear to be large. Mr. Gallop, who has prospected the gravels and sands in the vicinity of Sombrio River, reports the occurrence of native mercury in the sands. The mercury was probably derived from such deposits as are known to occur on Cinnabar Creek, near Sechart, on the northwest side of Barkley Sound.

### Vein and Impregnated Deposits.

Continuing, Mr. Clapp states that in the southeastern part of Vancouver Island many of the quartz-feldspar veins, which were probably formed during the intrusion of the upper Jurassic granitic rocks, have been prospected for gold entirely without success. The true nature of these veins, or apophyses, has apparently not been recognized; for since the feldspar has altered to sericite, it resembles on the weathered surface white milky quartz, and the veins have, therefore, the appearance of ordinary quartz veins. The veins also contain pyrite, which altering to limonite has stained the exposed surfaces, still further hiding the true character of the veins. On microscopic examination, feldspar is always seen to be present, and usually in excess. Such veins as these have not been shown elsewhere to be gold-bearing, and it is not likely, therefore, that they contain gold in commercial quantities in southern Vancouver Island, and their prospecting should be discouraged.

Mineralized shear zones occur throughout the limestone and meta-volcanics of the Vancouver group, but are best developed near the contracts with the intrusive granitic rocks. Similar mineralized shear zones also occur in the granitic rocks themselves, especially near the contacts. Deposits of this character are usually more important as possible sources of copper, but they also contain small amounts of gold. A typical example is the deposit on the Alfreda claim, situated on the east slope of Gordon River valley, three miles above the mouth. Here the diorite has been tremendously sheared, forming a shear zone about 25 ft. in width, which strikes N. 50 deg. W. The sheared diorite has the appearance of a chloritic or amphibole schist, but its true nature is readily recognized on microscopic examination. Although traces of the original minerals and texture are maintained, the sheared rock is composed chiefly of secondary minerals, which include sericite, uralite, biotite, muscovite, chlorite, and a little epidote. In the shear zone quartz lenses have been developed partly by replacement. The quartz of the lenses occurs in irregular, usually very small, grains, up to 2 or 3mm. in diameter. Associated with the quartz is a very little plagioclase feldspar and sericite. The quartz contains disseminated grains of pyrite and magnetite, which have altered somewhat to limonite, and is cut by later veinlets of quartz and calcite. The quartz rock is said by the owner of the claim, Mr. T. M. Baird, to assay $2 a ton in gold and 5 oz. of silver. Unless considerably larger bodies of higher-grade are found, these deposits are of little or no commercial importance.

# SPECIAL CORRESPONDENCE

## ONTARIO.

### COBALT, ELK LAKE AND GOWGANDA

The discovery of some high-grade ore on the old King Edward mine at Cross Lake now being operated by the York Ontario under a five year lease, is of some interest. Too much importance can easily be attached to the discovery in as much as the King Edward has always yielded pockets of high grade ore and very rich wall rock, but general values were too small to make much profit. The new vein reported is at the adit level running parallel to the No. 5 vein which was always the strongest in the mine. The mine in former days was always staffed and mined on the scale of a big property, now that it is being operated on the basis of a prospect with a small force of men and at a minor expense it may be made to yield a profit.

It is understood that the Beaver Consolidated which secured the property of the Erie Cobalt as a water reserve, may try to find some silver there. The Erie was once famous on the Cobalt stock market, but as far as can be ascertained never produced an ounce of silver. The condition of the Cobalt market is now such however that it appears worth while to revive even such faint hopes as the Erie.

Application has been made to the Mining Commissioner for permission to pump out Kerr Lake in order that the silver that undoubtedly lays under its waters may be mined. According to the plans filed it is proposed to place a raft on Kerr Lake and pump the water into Giroux Lake, but these are probably only provisionary, and other means of emptying the lake may be adopted. Which ever way is taken there appears little doubt that the famous lake will be made accessible to mining operations this year.

Kerr Lake has an extent of forty acres, and is possessed by the Crown Reserve, 32 acres; the Drummond, 6 acres, and the Kerr Lake 11 acres. At least one-third of the great Carson vein on the Crown Reserve between the bottom of the lake and the first level is intact and contains millions of ounces that will be liberated when the lake is drained. In addition all the other vein systems since found on the Crown Reserve in all probability come to the surface and can be mined. It is an extraordinary fact also that sixty per cent. of the total area of the Crown Reserve has not been prospected yet. Some of this sixty per cent. is in the fecund conglomerate though not much of it, and therefore in that respect its undeveloped territory is not as great as it would seem. As to the Kerr Lake the last annual report states that of 6,660,091 ounces total ore reserves, 2,781,400 ounces are under the lake. Thus the Kerr Lake have in a known ore body over a million dollars to mine under Kerr Lake. The Kerr Lake early in its history blasted into the bottom of Kerr Lake and had to close up the hole with a concrete dam and abandon the working. They were mining bonanza ore when this occurred too.

Large shipments of bullion continue to be made to England. In the middle of the month one hundred and twenty bars of silver worth $78,000 left on one day for Liverpool. The Buffalo and Nipissing were the principal contributors, the Cobalt Townsite and the Casey Cobalt despatching but 5,000 ounces between them. The high grade plant at the Buffalo is now running smoothly and henceforth all silver will go out in bars.

Mr. Thomas W. Gibson, Deputy Minister of Mines for Ontario, in a preliminary review of mining for the past year estimates the production of Porcupine at $2,000,000, four times the total output of Ontario for any previous year. It is probable that Mr. Gibson made his estimates before the scope of the strike at Porcupine was realized, and the output will be somewhat less than that. Also he based his estimates on Cobalt at 30,000,000 ounces before the returns for December from some of the mines had begun to be known and it is likely that it will be nearer 31,000,000 ounces than 30,000,000 ounces.

Minority stockholders of the Wettlaufer silver mine in Buffalo are not satisfied with the manner in which the present management is dealing with the situation and they are soliciting proxies for the annual meeting which occurs on Jan. 27. Since the resignation of Mr. H. Lindsley as manager, Mr. Robert Livermore, manager of the Kerr Lake, has assumed the direction of affairs.

The annual statement of the Temiskaming Mining Company just issued to shareholders goes to show that profit on the year's working was $413,615 against $271,423 in 1911. The same amount was paid in dividends, namely $300,000, but the extra profits were utilized in liquidating the debt on the purchase of the North Dome on Porcupine. The cash surplus shown at the end of the year was $590,591. The returns from ore shales and shipments amounted to $762,653, while there is $13,980 due from smelters and $48,010 of ore on hand.

The old Alexandra mine on the top of Diabase Mountain is being pumped out, and operations will commence from the 300-foot level soon. The success of the Bailey has been the prime factor in inducing this company to resume operations and they hope to pick up the Baileys leads. A small plant has been installed for immediate work.

The Northern Customs concentrator have thrown out their four Nissen stamps and replaced them with ten stamps of the ordinary type. This brings the total number of stamps dropping in the customs mill up to 120, and about 400 tons of ore are being treated daily. According to its contracts the mill has from four to five years' work ahead of it. The mill is at present treating ore from the La Rose, the Cobalt Townsite, and the Drummond. The La Rose has just renewed its contract with the Customs Company on the basis of a hundred tons of ore per day for the next four years.

**Porcupine, Swastika.**

It seems most probable that the shareholders of the Crown Chartered Mining Company will lose the Davidson property, their only claim of real value. Mr. C. F. Dike, who came from Cripple Creek, Colo., to look after Crown Chartered operations in Porcupine has severed his connection with the company, and has been retained by the General Assets Company of Montreal, to act in their interests. The General Assets control the Dome Lake mine in Porcupine and the Cochrane in Cobalt.

Excellent progress is being made with the erection of camp buildings on the Tough claims at Kirkland Lake, and Mr. C. A. Foster who holds a controlling interest in the properties will soon be in a position to make a real start at mining. So far mining operations have consisted in open cutting for 36 feet by 10 feet deep and taking out a carload of high grade ore.

There are now far more prospectors working in the townships surrounding Kirkland Lake than in any other portion of the Northern Ontario mining field. The discovery on the Tough claims and some others has made a very lively interest in this section. The township of Morissette Lebel and Teek are being staked in very largely. An hotel is being built at Kirkland Lake for the accommodation of travelers between that point and Swastika.

## COMPANY NOTES

### CROWN RESERVE REPORT.

The Crown Reserve has a surplus now of $821,000, compared with $764,000 at the end of last year. This is a very encouraging increase.

The cash on hand now amounts to $352,000, while there is also $251,000 due from the smelters, which is virtually cash. The total assets stand over $3,000,000.

The following statement presented to the shareholders is as follows:

| | | |
|---|---|---|
| Credit. | | |
| By ore production | | $1,692,060.76 |
| Debtor. | | |
| Mining expenses, development, depreciation, etc. | $343,387.88 | |
| Smelters' charges and deductions | 53,869.18 | |
| Bonus to employees | 10,882.96 | |
| Royalty, Ontario Government, accrued and accruing | 147,910.03 | |
| | | 556,050.05 |
| Profit | | $1,136,010.71 |

**Profit and Loss Account.**

| | |
|---|---|
| Cr. | |
| By balance from 1911 | $ 764,851.76 |
| By profit operating for 1912, as above | 1,136,010.71 |
| By interest from bank | 9,083.74 |
| | $1,909,946.21 |

| Dr. | | |
|---|---|---|
| To prospecting, explorations and operations, Silver Leaf Issue, etc. | $ 27,264.91 | |
| To dividends, 1912: | | |
| Nos. 24 to 35, inclusive | 1,061,288.40 | |
| | | 1,088,553.31 |
| Surplus | 821,392.90 | |
| Mining lands, minerals and mining rights, building plant and equipment, etc. | $2,076,102.72 | |
| Stores and supplies | 11,667,13 | |
| Ore on hand | 50,000.00 | |
| Due from smelters | 251,528.11 | |
| Cash on hand and in bank | 352,896.62 | |
| McEnaney purchase price payments, and development, etc. | 269,080.97 | |
| | | $3,011,275.55 |
| **Liabilities.** | | |
| *Capital stock | $1,999,957.00 | |
| Royalty accrued and accruing, Ontario Government | 72,018.96 | |
| Accounts payable | 29,465.99 | |
| Dividend due Jan. 15, 1913 | 88,440.70 | |
| Surplus | | $ 821,392.90 |
| **Assets** | | |
| | | $3,011,275.55 |

## GRANBY MEETING.

A special meeting of stockholders of Granby Cons. Mining and Smelting Co., Limited, has been ealled for February 25th, to authorize an issue of not more than $5,000,000 bonds convertible into ordinary shares at not less than par.

Of the proposed new issue, Granby plans to promptly offer $1,500,000 to shareholders, pro rata, at par and interest.

In order to provide for the eonversion of these bonds, capital stock will be increased from 15,0000,000 to 20,-000,000.

The Directors have also ordered the resumption of dividend payments by declaration of 1½ per eent., payable March 1st to stoek of reeord February 4th. For purposes of dividend and speeial stockholders' meeting transfer books, close February 4th, and re-open February 25th.

The proposed immediate issue of $1,500,000 has been underwritten by bankers for a reasonable commission.

The last dividend on the stoek was 1 per cent. and was paid on December 30th, 1910.

## HOLLINGER'S HALF-YEAR.

The six months' statement of Hollinger Gold Mines with the fourth dividend shows that for the half-year up to the end of 1912 it produced gold to the value of $970,340, and made a profit of about $750,000 from the 43,227 tons crushed, the detailed figures being:

| | |
|---|---|
| Gold bars | $859,475 |
| Precipitates on hand | 24,498 |
| Slags on hand | 13,500 |
| Gold in solutions | 24,500 |
| Bullion in hand | 12,000 |
| Value of gold recovered | $933,973 |
| Lost in tailings | 36,367 |
| Total value in ore | $970,340 |
| Ore milled— | |
| From development, tons | 23,404 |
| From stopes, tons | 19,822 |
| Total | 43,227 |
| Average value of ore, per ton | $22.45 |
| Percentage of value recovered | 96.3 |

The estimated profit for the period being $750,000, although final figures may alter this to some slight extent.

The labour troubles brought down the net profits considerably.

## LA ROSE FOR 1912.

With the end of 1912 closed a successful year for La Rose mine, the December figures of which are as follows: Shipments during December, $106,604; income for month, $163,128; operating expenses, $67,826; net profit for December, $95,301.

The total income for the year 1912 was $1,796,880, and the operating expenses $779,916, leaving a net profit for the twelve months of $1,026,663.

The actual cash surplus to December 31, 1912, was $1,667,104, which, with $199,526 in outstanding shipments and ore on hand, brings up the total surplus to $1,866,631.

## KERR LAKE.

Application has been made to the Ontario Mining Commissioners by the Crown Reserve Mining Company and the Kerr Lake Mining Company for permission to pump out Kerr Lake. Drummond mine is also interested.

The proposal is to pump the water out into the Giroux Lake, or if that is not practicable Gelin Lake, whenee it will flow into the Montreal River.

It is estimated that 2,781,400 ounces would be made available by the draining of the lake.

## JUPITER MILL.

The installation of the mill at the Jupiter property will, it is reported, be started about the first of April. It is decided that eyanide treatment will be adopted for the ore, but other details of the mill remain as yet indefinite. These details will be worked out and the plans perfected within a short time.

## TEMISKAMING PROFITS.

The net profits of the Temiskaming Mining Company for 1912 were $413,615, as compared with $271,423 in 1911. Total receipts were $776,075, of which $762,653 was from ore sales and shipments. The profit and loss aeeount showed a balance of $477,441 from 1911 and $413,615 net profits in 1912. Dividends paid in 1912 amounted to $300,000, and a balance of $590,591 is carried forward for the year.

## SENECA SUPERIOR DIVIDEND.

The directors of the Seneca-Superior Company have declared a 10 per eent. dividend, payable on February 15th, to shareholders of reeord February 10th. The career of the eompany, whieh was only organized in January, 1912, has been remarkable in the extreme. The eompany has now been shipping ore regularly for some time and the stock has made rapid advanees on the market and yesterday stood at as high as 1.85 bid at the close.

*231,143 fully paid-up shares of $100 each, of the above amount are held as the Trustees for the benefit of the company.

**Chambers-Ferland Circular.**—A circular has been sent out from the office of the Chambers-Ferland Mining Company, notifying the shareholders that an agreement has been obtained from the Ontario Government whereby the royalty heretofore payable to the Giverument has been cancelled and released, subject to a provision that in case any large or valuable body or bodies of ore be found whereby the company makes in any calendar year, beginning with the first day of January, 1912, such a net profit from its mining operations as will enable the company to pay to its shareholders out of the net profits for such year a dividend in excess of ten per cent., then in such event after making allowance for payment of such dividend, the Minister of Lands, Forests and Mines may require the company to pay a royalty not exceeding the 25 per cent. royalty payable under the agreements therefore in force.

# STATISTICS AND RETURNS

### COBALT ORE SHIPMENTS.

For the week, 11 mines were on the shipping list, sending out 14 cars of ore, of which 11 cars contained high grade ore. A shipment of high grade was made from the Bailey mine, while the Casey-Cobalt also appears sending out 30 tons of high-grade from New Liskeard. The Drummond has shipped a car of concentrates to Thorold this week. A car of low grade came from the Seneca Superior. La Rose, with two cars of high grade, including one car containing 55 tons, headed the list for the week.

Four mines contributed in bullion during the week, the entire list being shipped on Tuesday of this week, Nipissing, Buffalo, Townsite and Casey-Cobalt were the shippers.

The shipments in pounds for the week follows:

| | |
|---|---|
| La Rose, 2 high | 174,855 |
| Dominion Red. Co., 2 low | 119,785 |
| Cobalt Townsite, 2 high | 147,863 |
| Cobalt Lake, 1 high | 64,535 |
| Trethewey, 1 high | 58,600 |
| Bailey, 1 high | 40,000 |
| Peterson Lake (Seneca Superior), 1 low | 84,299 |
| Temiskaming, 1 high | 62,087 |
| Casey-Cobalt, 1 high | 60,000 |
| Drummond, 1 high | 40,000 |
| McKinley-Darragh, 1 high | 83,600 |
| | 937,974 |

The bullion shipments were:

| | Ounces. | Value. |
|---|---|---|
| Nipissing | 63,641.36 | $39,777.26 |
| Buffalo | 54,712.00 | 35,000.00 |
| Townsite | 2,770.00 | 1,750.00 |
| Casey-Cobalt | 2,394.00 | 1,520.00 |
| | 123,617.36 | $78,056.26 |

For the year to date the bullion shipments from the camp are:

| | Ounces. | Value. |
|---|---|---|
| Nipissing | 114,760.66 | $72,301.91 |
| Buffalo | 54,712.00 | 35,000.00 |
| Trethewey | 5,077.00 | 3,223.00 |
| Cobalt Townsite | 2,770.00 | 1,759.00 |
| Casey-Cobalt | 2,394.00 | 1,520.00 |
| Miscellaneous | 2,637.00 | 1,575.00 |
| | 182,450.66 | $115,378.91 |

### B. C. ORE SHIPMENTS.
### Week ending Jan. 11, 1913.

Production of ore in the Kootenay and Boundary district for the week ending January 11 was 51,246 tons and smelter receipts were 42,222 tons. For the two weeks ending in the new year the production totals 101,789 tons and the smelter receipts are 87,835 tons. Output in detail was:

| | | |
|---|---|---|
| **Slocan and Ainsworth.** | | |

### Cobalt Bullion for 1912.

The year's bullion shipments to date are as follows:

| | Ounces. | Value. |
|---|---|---|
| Nipissing | 3,929,954.28 | $2,391,357.31 |
| Crown Reserve | 451,770.87 | 256,905.50 |
| Temiskaming | 38,782.00 | 23,165.10 |
| O'Brien | 222,538.94 | 134,045.61 |
| Nova Scotia | 49,010.00 | 31,800.00 |
| Buffalo | 186,489.50 | 115,014.54 |
| McKinley-Darragh | 80,327 | 6,069.37 |
| Kerr Lake | 27,706.46 | 17,057.95 |
| Trethewey | 20,637.08 | 12,416.16 |
| City of Cobalt | 5,659.94 | 3,133.20 |
| Colonial | 1,698.00 | 1,018.00 |
| La Rose | 69,849.00 | 41,030.38 |
| Wettlaufer | 3,280.62 | 2,003.14 |
| Cobalt Lake | 5,256.88 | 2,989.75 |
| Right of Way | 505.50 | 273.00 |
| Cobalt Townsite | 8,582.55 | 5,362.00 |
| Drummond | 3,513.54 | 2,169.42 |
| Casey Cobalt | 940.00 | 574.00 |
| Dom. Red. Co. | 75,972.46 | 46,760.03 |
| Miscellaneous | 16,672.56 | 14,050.14 |
| Bailey | 14,050.50 | 8,816.65 |
| Penn-Canadian | 445.00 | 272.69 |
| Miller Lake | 946.00 | 788.00 |
| Totals | 5,311,476.49 | $3,117,984.45 |

### German Copper Consumption.

L. Vogelstein & Co. report the following figures of German consumption of foreign copper for the eleven months,—January-November—1912:

| | Tons. |
|---|---|
| Imports of copper | 191,993 |
| Exports of copper | 9,050 |
| Consumption | 182,943 |

During the same period of 1911, the quantity of 168,-096 tons was consumed. Of the quantity reported for 1912, a total of 166,307 tons was imported from the United States.

### YEARLY SILVER AVERAGES.

| | New York. cents. | London pence. |
|---|---|---|
| 1910 | 53.486 | 24.670 |
| 1911 | 53.304 | 24.592 |
| 1912 | 60.835 | 28.042 |

### YEARLY COPPER AVERAGES.

| | Electrolytic. | Lake. |
|---|---|---|
| 1911 | 12,376 | 12.634 |
| 1912 | 16.341 | 16.560 |

### SILVER PRICES.

| | New York cents. | London pence. |
|---|---|---|
| January 9 | 63⅝ | 29 5/16 |
| " 10 | 63⅝ | 29 5/16 |
| " 11 | 63⅝ | 29 5/16 |
| " 13 | 63½ | 29¼ |
| " 14 | 63⅛ | 29 1/16 |
| " 15 | 63⅛ | 29 1/16 |
| " 16 | 63⅛ | 29 1/16 |
| " 17 | 63 | 29 |
| " 18 | 63 | 29 |
| " 20 | 63⅛ | 29 1/16 |
| " 21 | 63 | 29 |

### GENERAL MARKETS.

Coal, anthracite, $5.50 to $6.75.

Coal, bituminous, $3.50 to $4.50 for 1¼-inch lump.

**Coke.**

January 21.—Connellsville Coke (f.o.b. ovens).

Furance coke, prompt, $4.00 per ton.

Foundry coke, $4.25 to $4.50 per ton.

January 21—Tin, Straits, 50.20 cents.

Copper, Prime Lake, 16.25 cents.

Electrolytic copper, 16.00 cents.

Copper wire, 18.00 to 18.25 cents.

Lead, 4.35 cents.

Spelter, 7.25 cents.

Sheet zinc (f.o.b. smelter), 9.00 cents.

Antimony, Cookson's, 9.60 to 9.70 cents.

Aluminium, 26.25 to 26.50 cents.

Nickel, 45.00 cents.

Platinum, ordinary, $46.00 per ounce.

Platinum, hard, $51.00 per ounce.

Bismuth, $2.00 to $2.25 per lb.

Quicksilver, $40.00 per 75-lb. flask.

# PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assaye. Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

### ANNUAL MEETING

The Annual General Meeting of Shareholders of this Company will be at the Head Office of the Company, 103 Bay Street, Toronto, on SATURDAY, FEBRUARY 15th, 1913 at 11 o'clock in the forenoon for the reception of the Financial Statement and Report of the Directors for the past year and for the election of Directors and for the transaction of such other business as may be brought before it.

AND TAKE NOTICE that a dividend of ten cents a share has this day been declared on the outstanding shares of the Company, said dividend to be paid on the 15th day of February next to the shareholders of record at the close of business on the 10th day of February, 1913.

By order of the Board,
R. F. SEGSWORTH,
Secretary-Treasurer.

Toronto, January 18th, 1913.

# DEPARTMENT OF MINES GEOLOGICAL SURVEY.

## PUBLICATIONS

**The Geological Survey has published maps and reports dealing with a large part of Canada, with many local areas and special subjects.**

A catalogue of publications will be sent free to any applicant. A single copy of a map or report that is specially desired will be sent to a Canadian applicant free of cost and to others at a nominal price. The applicant should state definitely the Precise area concerning which information is desired, and it is often of assistance in filling an order for a map or report if he states the use for which it is required.

Most of the older reports are out of print, but they may usually be found in public libraries, libraries of the Canadian Mining Institute, etc.

### REPORTS RECENTLY ISSUED:

CANADA

1085. Descriptive Sketch of the Geology and Economic Minerals of Canada. Accompanied by a geological and mineral map of Canada, by G. A. Young and R. W. Brock.
1218. Summary Report of the Geological Survey for 1911.

NEW BRUNSWICK and NOVA SCOTIA

1113. Memoir No. 16. The Clay and Shale Deposits of Nova Scotia and portions of New Brunswick, by H. Ries and J. Keele.

QUEBEC

1110. Memoir No. 4. Geological reconnaissance along the line of the National Transcontinental Railway in Western Quebec, by W. J. Wilson, accompanied by a map.

ONTARIO

1213. Memoir No. 28. The Geology of Steeprock Lake, Ontario, by Andrew C. Lawson. Notes on Fossils from Limestone of Steeprock Lake, Ontario, by Charles D. Walcott.

NORTH WEST PROVINCES

1204. Memoir No. 24. Preliminary Report on the Clay and Shale Deposits of the Western Provinces, by Heinrich Ries and Joseph Keele.
1211. Memoir No. 27. Report of the Commission appointed to investigate Turtle Mountain, Frank, Alberta, 1911.

BRITISH COLUMBIA

940. Report on Graham Island, B.C., by R. W. Ells. (Reprint.)
1121. Memoir No. 13. Southern Vancouver Island, by Charles H. Clapp.
1175. Memoir No. 21. The Geology and Ore Deposits of Phoenix, Boundary District, B.C., by O. E. LeRoy.

YUKON and NORTH WEST TERRITORIES

080. Report on a part of the North West Territories drained by the Winisk and Attawapiskat Rivers, by Wm. McInnes.

### MAPS RECENTLY ISSUED:

CANADA

942. Mineral Map of Canada. Scale 100 miles to 1 inch.

NOVA SCOTIA

1133. Map 13A. Kingsport sheet, Nova Scotia, No. 84. Scale 1 mile to 1 inch.

NEW BRUNSWICK

1181. Map 35A. Reconnaissance Map of Parts of Albert and Westmorland Counties, N.B. Geology and topography. Scale 1 mile to 1 inch.

QUEBEC

1112. Map 12A. Vicinity of the Tranco ntinental Railway, Abitibi District, Quebec. Scale 4 miles to 1 inch.
1178. Map 32A. Larder Lake and Opasatika Lake, Nipissing, Abitibi and Pontiac, Ontario and Quebec. Geological. Scale 2 miles to 1 inch.

ONTARIO

964. Geological map of portions of the districts of Algoma and Thunder Bay, Ontario. Scale 8 miles to 1 inch. Second edition.

ALBERTA

1132. Map No. 7A. Bighorn Coal Area, Alberta, by G. Malloch. Scale 2 miles to 1 inch.

BRITISH COLUMBIA

792. West Kootenay sheet, B.C. Geological. Scale 4 miles to 1 inch.
1167. Map 29A. Mother Lode and Sunset Mines, Deadwood, B.C., Topographical. Scale 400 feet to 1 inch.
1147. Map 19A. Lardeau, West Kootenay, B.C. Topographical scale 4 miles to 1 inch. Contour interval 500 feet.
1197. Map 47A. Law's Mining Camp near Tulameen, B.C. Geological. Scale 600 feet to 1 inch. Contour interval 50 feet.
1219. Map 54A. Nanaimo Coal Area, Vancouver Island, B.C. Scale 1½ miles to 1 inch. Contour interval 100 feet.

YUKON and NORTH WEST TERRITORIES

1089. Map 9A. Explored Routes on Parts of the Albany, Severn and Winisk Rivers. Scale 8 miles to 1 inch.

NOTE.—Maps published within the last two years may be had, printed on linen, for field use. A charge of 10 cents is made for maps on linen.

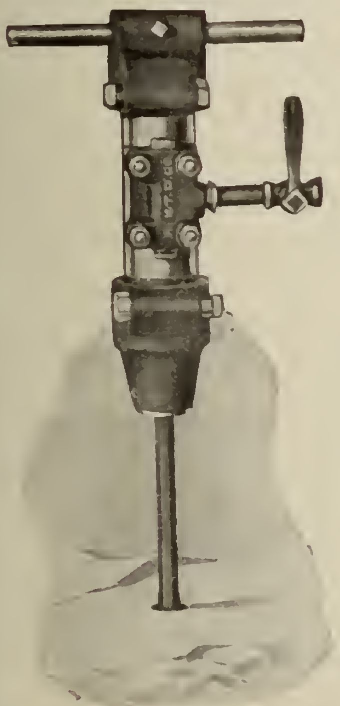
The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon. Letters and samples that are of a Departmental nature, addressed to the Director, may be mailed O.H.M.S. free of postage.

*Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.*

# BUYERS AND SELLERS OF METALS

# McKIERNAN - TERRY
# Rock Drills

**It will pay you to investigate our line of McKiernan-Terry Wizard Rock Drills, with Cushioning Device and Corliss Valve, also**



96 lb. Shaft Sinking Hammer Drills.

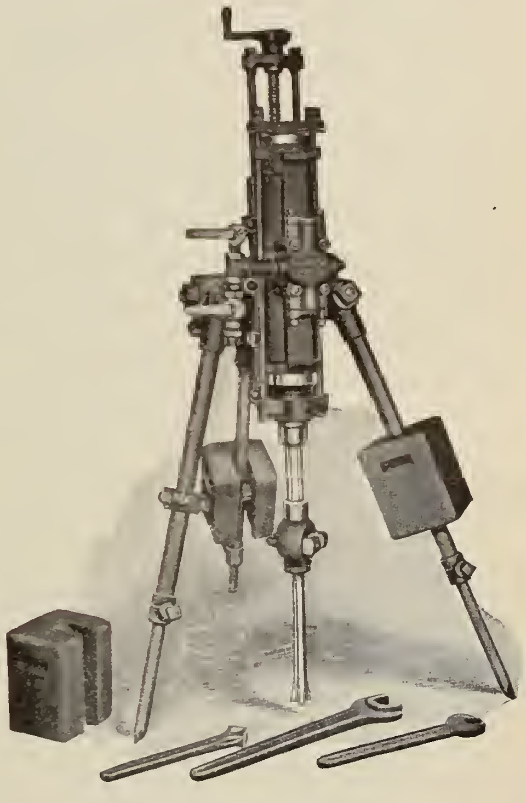
80 lb. Class "A" Self-Rotating Hammer Drill.

52 lb. Class "B" or 'Busy Bee' Hammer Drill.

27 lb. Class "C" or 'Plugger' Hammer Drill.

Class "D" Stoping Drill with Telescope Feed.

Pile Hammers for Driving Sheet Piling.



**CORE DRILLS—Any size Core, any depth Hole**

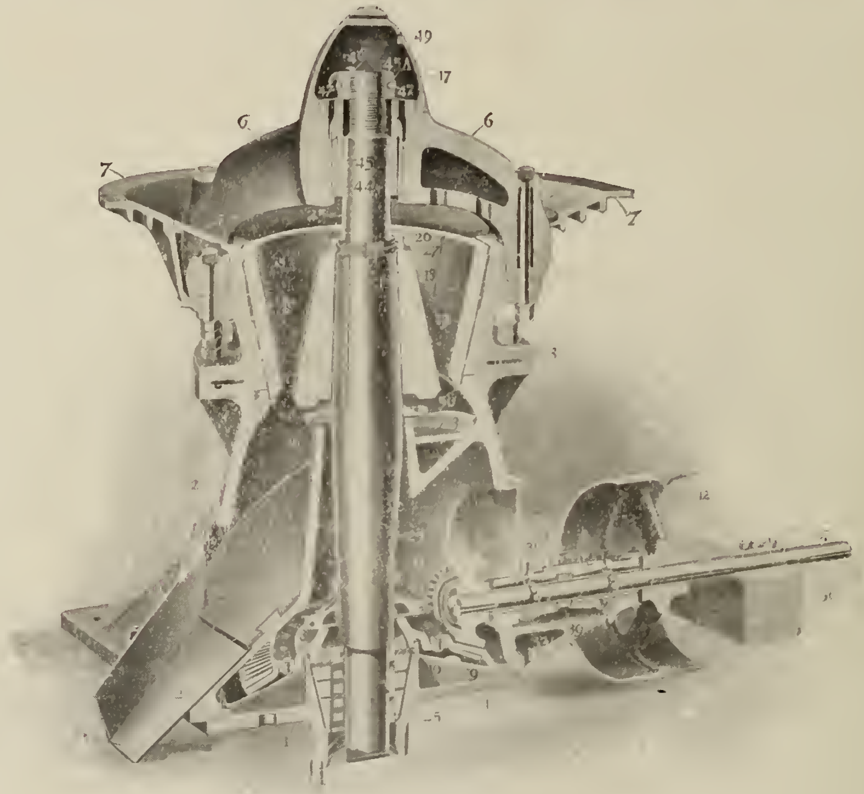
*THE OLD RELIABLE*

# GATES "K" BREAKER



SECTIONAL VIEW OF GATES "K" BREAKER

## WAY GATES "K" BREAKER IS BEST

REQUIRES LEAST POWER TO OPERATE:—This machine will break more rock per horse power than any other ever made.

EASE OF FEEDING:—The style of spider gives large and unobstructed feed openings which do away with clogging and consequent loss of time in working.

UNOBSTRUCTED DISCHARGE:—No limit of capacity at this point.

HIGHEST RANGE OF ADJUSTMENT:—Provides ease in changing the sizes of product and great facility for taking up wear of the breaking surfaces.

TOP SUSPENSION OF SHAFT:—Prevents the bottom bearings running hot under the hardest work and makes adjustments easy.

STRENGTH AND RIGIDITY:—Due to the liberal proportioning of the parts.

COOL RUNNING:—Because of extra large bearings.

EASE OF MAINTENANCE:—Every detail has been carefully worked out and every part particularly designed to do its work. Each part is easily accessible.

CONCAVES CAN BE CHANGED WITHOUT DISTURBING THE SPIDER OR HOPPER:—Impossible with any other style of breaker.

# SEND FOR BOOK OF PLANS

## Homes to Suit All Purses

We have prepared a very comprehensive book giving actual illustrations and floor plans for 60 inexpensive homes, not of the portable variety, but built for comfort, summer and winter.

If you anticipate building you need this book. You will eliminate the expense of preparing plans, and save more money in the construction of your home—you will save three dollars out of every ten of total expense.

Our homes have been erected with great success in various parts of Canada, and in every case at a tremendous saving in cost. No experience is required to erect.

## "Readi-Cut" Houses

All material is supplied cut to exact size all marked to correspond with the simple plans and directions. We supply complete materials for homes from $110 upwards.

The book is FREE to those who contemplate building their own home. All we ask is that you send 6 cents to cover postage. Write to-day for booklet No.69, Address

# DESIGN OF MINE STRUCTURES

By MILOS. KETCHUM, CE., Dean of College of Engineering, University of Colorado.

460 *pp.*, 265 *illus.*, $4.00 (17*s*) *net, postpaid.*

Dean Ketchum's books have been in wide demand. They have met the needs of practical engineers not only because of their clear treatment of theory and for the real designs, but because of the data and details of construction, costs, etc.

This new volume covers the design of head frames, coal tipples, coal washers, coal breakers, concentrators, mine buildings, bins, retaining walls, trestles and other mine structures made of steel, timber and reinforced concrete.

## WALLS, BINS, AND GRAIN ELEVATORS

*Second Edition—fully revised*, 556 *pp.*, $4.00 (17*s*) *net. postpaid.*

This standard work has in its new edition complete, modern material on design and construction. It has entirely fresh material on "Reinforced Concrete" and "Methods of Construction and Cost of Retaining Walls."

## DESIGN OF STEEL MILL BRIDGES

464 *pp.*, $4.00 (17*s*) *net, postpaid.*

## DESIGN OF HIGHWAY BUILDINGS

550 *pp.*, $4.00 (17*s*) *net, postpaid.*

# Sullivan Air-Jet Sinkers

## For Shaft Sinking,

under many conditions, you can save time, power and labor by using a few Sullivan "Air-Jet Sinkers."

These sturdy, smooth-running hammer drills are equipped with hollow steel, through which air is forced to clean the holes.

Sullivan "Air-Jet Sinkers" are built in two sizes—"DB21," 60-pounds, for eight-foot holes; "DC19," 45-pounds, for six-foot holes.

# FOUR GREAT MINING BOOKS

### Mining Without Timber

By
**Robert B. Brinsmade**
309 pp., illus., $3.00

This is the first book on those modern mining methods which require the minimum of timber.

Mr. Brinsmade has collected all the best material which has appeared to date. It covers the various methods of leading mines. It is full and complete on Open Cut, Stoping, Back Caving, Block Caving, Slicing, etc.

### Timbering and Mining

By **W. H. Storms.** 300 pp., fully illustrated, $2.00 (8/6).

A practical treatise on American methods. Mr. Storms has written the matter in a clear, straightforward way, and kept in mind, always, the practical and economical features.

### Cost of Mining

By **James R. Finlay.** 415 pp., illustrated, $5.00 (21s).

The results of the leading mines of the world are presented in this book. It gives detailed analysis of the costs of mining coal, iron, lead, zinc, copper, gold and silver.

### Principles of Mining

By **H. G. Hoover.** 200 pp., illustrated. $2.50 (10/6).

The standard treatise. The three parts are: First—The valuation. Second—The development of tunnels, shafts etc., with valuable material on equipment and efficiency. Third—The administration of mines, problems of labor, efficiency, costs, etc.

## MINING AND POLITICS

The time has come for painfully plain speech about the attitude of the Dominion Government towards the mining industry. Despite the fact that the claims of that industry have been repeatedly put forward, and despite the further fact that the justice of those claims has been proved, the Government, through dilatoriness, indifference, or weakness, continues its policy of neglect.

Since the present Government was put in power, quasi —the Department (or, rather, the Department) of Mining has been blessed with no less than four changes of Ministers. Messrs. Nanton, Rogers, Roche, and Coderre have successively been appointed to this responsible position. Not one of these gentlemen has anything approaching adequate knowledge of the industry. It follows, therefore, that not one was appointed for the benefit of mining, and that only considerations of expediency influenced the situation.

There has been ample mincing of words and phrases heretofore. The Canadian Mining Institute, through its delegations and at its meetings, has voiced the desire of the mining man for better treatment. Whilst its delegates have walked softly and talked politely, they cannot have failed to impress upon the Rt. Hon. Mr. Borden and his Ministers the fact that the Institute as a whole deplores and resents the futility of the past and present situations. Briefly, therefore, the treatment accorded the mining industry appears to be calmly deliberate.

This being the case, there is only one course to pursue. The Canadian Mining Institute has a membership of over one thousand. Its representations to the Government have been without avail. It behoves the members, therefore, to use other means to obtain their rights. And the only means left is the exercise of whatever definite and legitimate political influence they may possess. In short, the members of the Institute and the mining community at large must realize that as a body they cannot afford to have their just claims repeatedly ignored. While there may be no necessity for using threats, it certainly is clearly necessary to demonstrate to the Government that mining men are a strong factor in determining political fortunes.

The forthcoming annual meeting of the Canadian Mining Institute should be made memorable by the formulation of a Bill of Rights. We have definite grievances. The Institute, which is the only national organization representing the industry, must assume the duty of presenting these grievances forcibly and completely. While, of course, the amenities will be regarded, our claims can no longer be put forward as nebulous suggestions; they must be clothed in positive and categorical language. The industry of mining must assert itself.

It is not compatible with the dignity of the industry that its departmental head in Ottawa should be chosen for merely political reasons. He should be first and always a mining man. If such a person be not available in Parliament there is nothing to deter the Government from making a selection outside. This has been done in several notable instances, and never has there been better reason for repeating the step.

If the Institute seizes this chance of facing facts firmly it will have conferred a lasting benefit upon the nation.

At present the second largest industry of Canada is without representation in the House of Commons or in the Senate, and its ministerial administration is a negligible quantity.

---

## THE CANADIAN MINING INSTITUTE ANNUAL MEETING

Owing to the fact that certain officials of the Geological Survey have conspired together to enliven the approaching annual meeting of the Institute at Ottawa, it may be readily believed that the visitors will suffer no boredom. The smoker and the dinner, which, after all, are the main features of the meeting, will be enlivened by flashes of geological wit, and by infusions of departmental humour.

The gathering is to be formally opened by His Royal Highness the Duke of Connaught. Then will follow the regular routine of presenting Dominion and Provincial statistics, etc. Among the papers to be read during the afternoon session are several dealing with the mineral industries of the Ottawa district. These should be the most instructive. The evening session will be devoted to a lecture on Yukon Territory, by Dr. Henry M. Payne. Dr. Alfred M. Thompson, M.P., will occupy the chair and will also speak on the same subject. During the remaining session the papers read will be remarkably well chosen and varied. Speaking generally, they will be of much more practical interest than many of those presented on previous occasions. In fact, if we may judge by the titles, the Secretary is to be congratulated upon securing a fine list of subjects. Certain malign spirits will learn with joy that few geological essays are to be inflicted on unwilling ears. It is not known whether this is or is not a concession to stiff-necked Philistines.

. . . . .

We hope and believe that every attending member of the Institute will do what in him lies to contribute to the success of each and every session. Much earnest thought has been given to this meeting. It is very necessary that the attendance be as large as possible. It is equally necessary that the proceedings be as animated as they can be made.

Let us get together and see that a record attendance is assured, and that discussion never lags. We owe it to the officers of the Institute, to the Institute itself, and to our official hosts in Ottawa, to make a good showing.

## TWO NOTABLE PAPERS

Six times a year the American Academy of Political and Social Science publishers a substantial volume of essays covering a wide range of apposite subjects. The last volume is wholly devoted to things Canadian. Reciprocity is discussed by the Hon. Clifford Sifton—who probably knows what he is writing about better than most authorities. Canadian banking is tackled by Mr. H. M. P. Eckardt, who is, perhaps, a trifle fulsome in his appreciation of our lop-sided system. Mr. J. Castell Hopkins is equally appreciation of Canadian literati. He tabulates many of our ephemeral performers and is generously inclusive. An Englishman, Mr. W. A. Chapple, M.P., describes us as a hospitable and not unintelligent race, which, by the way, makes us feel deucedly cocky. Other writers discourse upon various other phases of our national life.

The two papers, however, that interest us most are from the pens of Dr. G. A. Young, of the Geological Survey, and Mr. J. M. Clark, K.C., of Toronto. Dr. Young writes on the hackneyed theme, "The Mineral Resources of Canada," and does so very creditably. Mr. Clark's paper is entitled, "Mining Legislation in Canada."

Writing for non-Canadian readers, Dr. Young naturally has to include in his essay much material that to our informed minds may appear trite and worn. In fact, we never have coveted the task of expatiating on this particular subject. But it is to Dr. Young's credit that he has been nimble enough to make his article clear, readable, and comprehensive. After tracing the phenomenal growth of Canada's mining industry and, by means of vivid comparisons, impressing its recent expansion strongly upon the reader, Dr. Young dwells upon the untouched regions of Canada. "In the imperfectly prospected and unprospected regions there is an almost unlimited area over which the geological conditions are similar to those of districts of known mineral wealth. The presence of like geological conditions implies the existence of like mineral deposits, for experience has demonstrated that the mineral deposits of any grown districts have resulted, directly or indirectly, from the action of the same general forces that gave rise to the broader geological structures and features of the region. Therefore, in order to indicate approximately only the probable extent and value of the mineral resources of a country, it is necessary to give at least a broadly generalized description of its geological features." This generalized description follows, and it is an excellent bird's-eye view of Canada's geological features. Each of the six great geological regions, or provinces, is described, and the characteristic deposits of each are mentioned. The essay concludes thus:—"Only in the comparatively limited area extending eastward from the St. Lawrence valley is the annual production in any way commensurate with the known mineral resources of the country. And even in this eastern region, the discoveries of late years have indicated the existence of previously unsuspected classes of mineral deposits. Over nearly the whole of the vast area of Canada the mineral "resources at present being developed are confined to "very limited areas bordering the main routes of travel. "Even within these circumscribed areas it is indisput- "ably known that great stores of mineral wealth still lie "untouched or undiscovered."

Mr. Clark's essay is entirely different in character from Dr. Young's. The writer's object is to trace the growth of our mining laws and to show the relations existing between Federal and Provincial legislation. He recognizes the unequal, sketchy, and clumsy nature of the present laws, and emphasizes the need of sounder and more comprehensive enactments. Referring to the proposed Federal mining law, Mr. Clark says:—"The "framing of this general law is regarded by mining men "as supremely important, not only on account of the great "interests actually and potentially involved, but also be- "cause it is looked upon as the first step towards the uni- "fication of the mining laws of Canada. The vital im- "portance of such completeness, wisdom, and practical "convenience being embodied in the Federal statute as "will recommend it to the several provinces for volun- "tary adoption is therefore self-evident."

An allusion to the "apex-law" is also interesting. It runs thus:—"There is no danger that the so-called 'apex "law' will be again introduced into Canada. That law "was copied under the influence of miners from the Pa- "cific States, by British Columbia, but was finally abol- "ished April 23, 1892. . . . . The vested rights of claim "owners who had located their claims under former acts "were protected; and the 'apex law' in British Colum- "bia, as elsewhere, has given rise to costly litigation, "which seems inherent in the system of extra-lateral "rights."

As to the problems of "blanketing," taxation, and royalties, Mr. Clark points out, that has the present opportunity of "taking full advantage of the results of min- "ing codes in other countries and of her own unique ex- "perience of various systems of law."

The three essentials are "generality, equality, and certainty." And the greatest of these, says Mr. Clark, is certainty.

## EDITORIAL NOTES

Whether the shortening of working hours in Cobalt was or was not a strategic move, it was commendable. Any reasonable concession to prevent a strike is worth while. It is deplorable, however, that the miners of Northern Ontario are so helplessly in the hands of parasitic labour-union demagogues. The men, if left to themselves, would steadily improve their condition without antagonizing their employers. As for the demagogues, an occasional strike is a necessity if for no other reason than that they may handle the strike funds. We firmly believe that a public investigation of the administration of labour-union funds is urgently required.

Conditions in respect of the Quebec asbestos industry improved greatly of late. There is now a considerable demand for fibre; and, notwithstanding the fact that the production in 1912 was the heaviest on record, stocks, we are informed, are practically depleted.

In an editorial note, in the last issue of the Mining Magazine, commenting on a recent meeting of the Institution of Mining and Metallurgy, the remark is made that really good papers do not provoke discussions; whereas "poor papers stir the combative and controversial powers of an audience to a degree highly beneficial in so far as they tend to balance the inadequate treatment of any subject by supplementing a paper with a discursive and illuminating discussion." Broadly speaking, this is true; but then from the technical society's standpoint the poor paper becomes the good paper, for the principal raison d'etre of a paper submitted for discussion should be to provoke discussion. Fortunately, however, we may have a "good" paper, that is to say an informative and intelligently written paper, provocative of controversy. "The Domes of Nova Scotia," contributed last year by Mr. T. A. Rickard to the Canadian Mining Institute and to the Institution of Mining and Metallurgy, was without doubt an excellent paper, nevertheless it was not received in silence. No one has made a better case for the inorganic origin of petroleum than Mr. Coste, in the several papers he has contributed to the Canadian Mining Institute, yet who will forget the expostulatory storm for which the elucidation of his theories was responsible. We are not altogether inclined to agree, therefore, with the opinion that "really good papers do not provoke discussion."

Neither diamonds nor placer gold has been found on the shores of Hudson's Bay by the several parties that have voyaged to look for it. Morever, the Quebec Government has just issued a report which declares that it will be quite useless to look for the precious stones in the blue clay of the great clay belt, inasmuch as it has an entirely different origin from that wherein the diamonds are found in South Africa.

Partly through the generosity of Dr. James Douglas the Kingston School of Mining has been enabled to extend its tutorial system. At present some twenty tutors are employed.

According to the estimates of L. Vogelstein & Co., the consumption of lead in the United States increased 15 per cent. during 1912. The total consumption approached 460,000 tons. The production from domestic sources was about 400,000 tons, the difference being drawn from stocks on hand. This reduces the working balance to a smaller amount than has been recorded since 1907.

Mr. Malcolm McNaughton, of the Dixon Crucible Co., in an article appearing in the Engineering and Mining Journal, after asserting that Ceylon remains the important source of crystalline plumbago, and that nowhere else in the world does the material occur where the conditions are such that it can be mined with profit, states that during the last twenty-five years some forty projects for the production of flake graphite have been initiated in the United States and Canada, of which only three are at the present time in full operation. The reason for the non-success of these undertakings is ascribed to verious causes, but chiefly to lack of resources or of knowledge of market conditions. Mr. McNaughton remarks, however, that the capacity of the mills on this continent is from eight to ten times greater than the present demand for flake graphite. The difference between the American and the Ceylon graphite is apparently that of structure. The former occurs as thin flakes disseminated throughout the rick, requiring an elaborate system of crushing and concentration for their separation. The resulting flakes are extremely thin, while the Cox prepared Ceylon plumbago is more granular in structure.

---

The Engineering and Mining Journal states that the trade in cobalt oxide is closely controlled. Prices during 1912 remained stationary at 80 cents per pound, but an increase to 90 cents has been announced to apply to 1913 contracts. The main imports of the United States are derived from the subsidiary companies of the International Nickel Corporation. It is stated that there is some recovery of cobalt from the ores of the Cobalt district, but by no means to the extent possible if warranted by a wider general use of the metal. It is meanwhile reported that there are over 3,000,000 lbs. of cobalt-nickel residues at Canadian and American refineries at which Cobalt district ores are treated. In view of the possibilities, the result of the experiments now being conducted by Dr. H. T. Klamus, at Kingston, under the auspices of the Dominion Department of Mines, to determine the value of cobalt as an alloy for steel and other means of utilization, are awaited with much interest.

---

## METAL LINER FOR TUBE MILLS

The Komata tube mill liner, which consists of a series of plates and lifting bars, first introduced in New Zealand at the Komata Reefs mine several years ago, is now being used in mills in America. The angle bars which form the ribs of the liners are of manganese steel, and liner plates of the same composition as usually recommended, though they can be made of either semi-steel, white, grey or hematite iron. The filler bars, which are placed underneath the angle bars and are not exposed to wear, are of soft cast iron. The several pieces of the liner are fastened to the shell of the mill by means of square-headed taper bolts. The ribs or angle bars are spaced about 18 or 20 inches apart, according to the diameter of the mill. It is claimed for this liner that (1) it gives a maximum area of mill, and, therefore, increased capacity; (2) absence of slipping of pebbles on the liner results in prolonged life of the liner, the prevention of flattening of the pebbles, and the avoidance of much waste power: (3) by reason of the cascading action of the pebbles their spherical shape is maintained, and this rolling action of the pebbles produces a greatly increased grinding action; (4) the consumption of pebbles or flints and the amount of power required per ton of sand are small; (5) the metal is distributed to give the greatest amount of life and the least amount of scrap when worn out; (6) it alters but slightly as regards thickness and shape, which means constant peripheral speed on the inside of the liners and uniform efficiency; (7) it is easily and quickly installed and repaired; (8) it can be cast at local foundries of semi-steel, white, grey or hematite iron.

## TUBE MILLS AT NEW PRIMROSE MINE

Two tube mills of standard size, 22½ by 6 feet, have recently been added to the New Primrose mine's equipment. The "South African Mining Journal" remarks that "the putting in of tube mills at this fine old property affords an interesting commentary on the manner in which the New Primrose is opening up. A few years ago the mine was believed to have but a limited life; in fact, estimates framed just after the conclusion of the war gave one to suppose that by the end of the current year the mine practically would be exhausted. Recently developments have been so eminently satisfactory that the management decided to augment and modernize the reduction plant, and there appears to be every prospect of the company contributing a substantial quota to the dividend list for a number of years to come.

---

## INTERNATIONAL GEOLOGICAL CONGRESS

### Suggested Programme for the Twelfth Session.

In a recent circular the Organization Committee of the International Geological Congress has outlined a provisional programme for the Toronto meeting. The general meeting will be held in Convocation Hall, Toronto University, while for the sectional meetings numerous lecture rooms are available. The division into section will probably be as follows:

**Section 1.** Sub-section a—Pre-Cambrian Geology.
" b—Economic Geology.
" c—Peliology, Mineralogy, etc.

**Section 2.** Palemtology, Mineralogy, etc.

**Section 3.** Glacial Geology and Physiography.

On the evening of Wednesday, August 6th, at 8 o'clock, an informal reception and re-union will be held in Convocation Hall.

On Thursday morning, after a conference of the Council of Organization, the formal opening will take place, probably presided over by the Duke of Connaught. The retiring and incoming Presidents and Secretaries of the Congress, the President of the university of Toronto, and his Worship the Mayor of Toronto will give addresses.

At 3 o'clock on Thursday afternoon, discussion of the major topic of the coal resources of the world will be commenced.

In the evening a public address will be given in Convocation Hall.

For a full week thereafter on each day there will be held general and sectional meetings, and a long series of excursions. On the second last evening a banquet will be given in honour of the visitors.

---

## SILVER COINAGE IN INDIA

Mr. Harold Baker (Financial Secretary, War Office), replying for Mr. Montagu, Under-Secretary for India, to a question by Mr. Bigland (U., Birkenhead), says: The amount of silver coined in 1911-12 at the Indian mints was as follows:

| | Standard ounces. | Equivalent in fine ozs. |
|---|---|---|
| Whole rupees, re-coined .. | 9,107.934 | 8,424.839 |
| Whole rupees, new ....... | nil | nil |
| One-half, one quarter, and one-eighth rupees, new ...... | nil | nil |
| One-half, one quarter, and one-eighth rupees, re-coined. | 405,829 | 375.391 |
| British dollars ........... | 31,596,753 | 29,226,997 |

The British dollars were coined at the requisition of banks. There is no "issue price," since the mint merely coin the silver tendered by banks and issue the dollars to the banks charging 2 per cent. for the work done.

# CORRESPONDENCE

## INTERMITTENT CYANIDATION

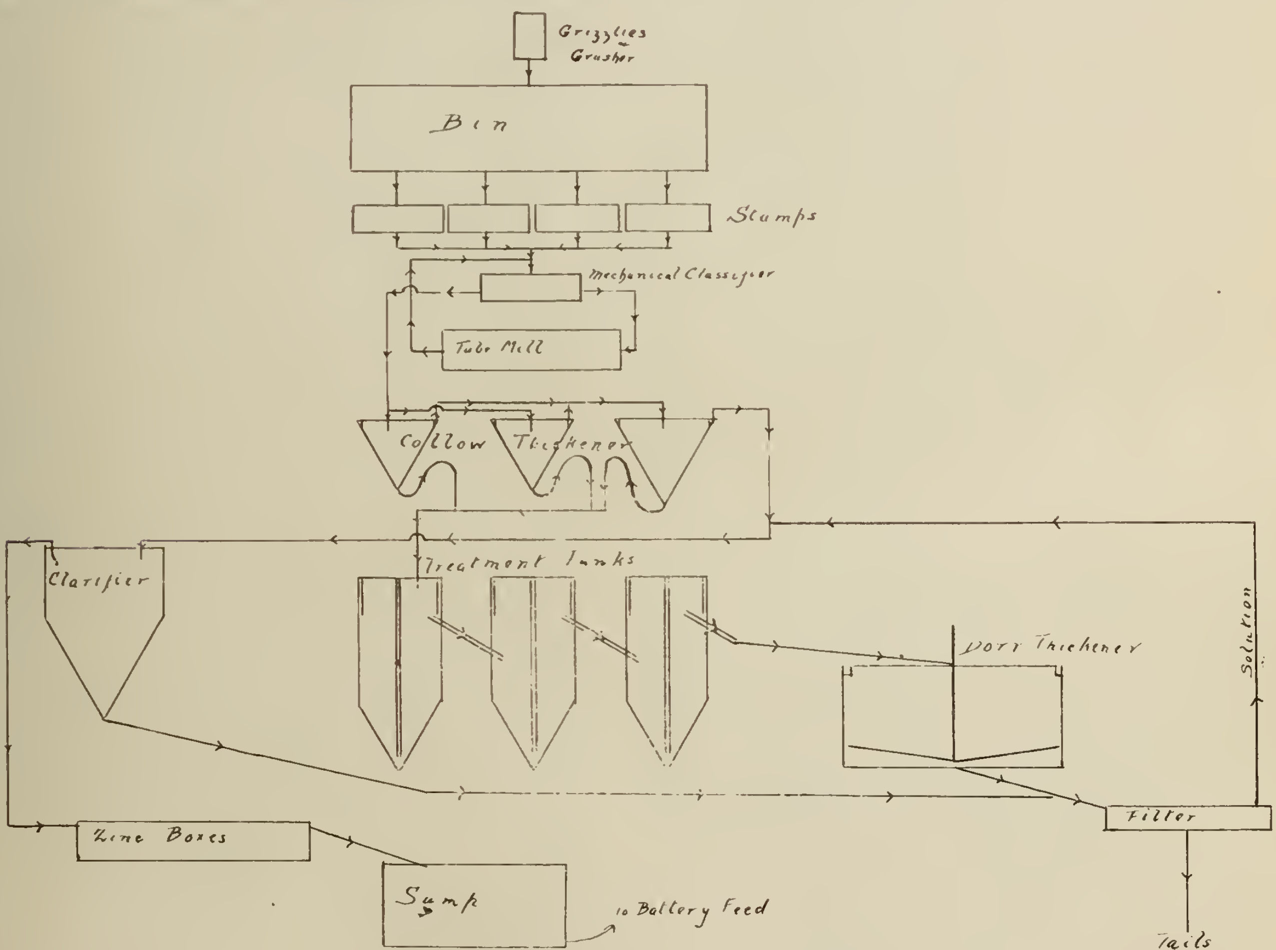
Editor The Canadian Mining Journal, Toronto:

Sir,—Mr. Leon P. Hill's article is of considerable interest to many metallurgists and raises questions upon which there is a great divergence of opinions.

It may be that theoretically the charge system surpasses the continuous, but I venture to say that in many cases theory and practice are at variance with one another, and as far as Mr. Hill's statement as to the popularity of the continuous system goes I should say that there is a direct verdict in favour of such a system and that it has been approved by many metallurgists. In his assumption of a series of 100-ton tanks, These show a tendency of the finer particles to go through the tanks, after some adjustment and on somewhat coarser material hardly and difference was shown as follows:

| | Influx to first tank. Pct. | Efflux from third tank. Pct. |
|---|---|---|
| On 100 mesh ........ | 12.4 | 12.0 |
| On 150 mesh ........ | 61.0 | 62.0 |
| On 200 mesh ........ | 12.4 | 11.6 |
| Through 200 mesh .... | 14.2 | 14.4 |

My idea of a continuous plant would have a flow sheet as follows:



Mr. Hills gives some figures which are no doubt correct, but he states that the heavier and coarser particles make the most rapid transit through the series. This I do not agree with, my experience has been the reverse, namely that the finer and lighter particles will pass most rapidly through a series of tanks, thus giving the heavier and coarser particles the longer treatment which is in some cases required; at the same time I should say that the most ideal system would be one which shows an even flow of all sizes of particles.

The following are a set of figures which were obtained from a set of three tanks on the continuous system using both air and centrifugal pump agitation:

| | Pct. | Pct. | Pct. | Pct. |
|---|---|---|---|---|
| On 100 mesh ....... | 7.9 | 6.6 | 3.6 | 2.8 |
| On 150 mesh ....... | 18.8 | 12.8 | 9.4 | 9.6 |
| On 200 mesh ....... | 16.2 | 22.4 | 26.2 | 25.8 |
| Through 200 mesh... | 57.0 | 58.2 | 60.8 | 61.8 |

The treatment tanks would be a modification of the Pachuca and Patterson having both air and centrifugal pump agitation, through a central column, and having a baffle which gives a circumferential quiet zone, this zone would have a double use, one for decanting and the other for pump suction, thus saving pump liners by not having any grit going through. The three callow thickeners would be used as follows: Two would take the direct overflow from the classifier, the thickened product going to treatment tanks. The overflow from these two goes to the third callow which would be somewhat larger than the others, the thickened product from this also going to treatment tanks and the overflow which would be fairly clear to the clarifier. This clarifier should be one of the canvas leaf system which not only takes the solution from callows, but also solution from Dorr thickener and filter, ensuring a perfectly clear and clean solution for the zinc boxes. Again, if any slime should get in the clarifier this would be let out occasionally to the Dorr thickener or filter. The filter used could be either pressure of vacuum. The choice rests with the person who supervises the putting up of the plant. Personally I like a Butters or Moore but have no data to offer on these filters.

The merits of such a system as this are, I think, far superior to those of the intermittent system, inasmuch as the time factor of settling and decanting on the intermittent as described by Mr. Hills would be enormous, and sufficient tank capacity must be provided to take the ore while the first or second tanks are undergoing this settlement, etc. Again, in his system of charging the tanks I should say that the finer and lighter particles would find their way more rapidly to his washer than would be expedient. I also notice that Mr. Hills has the washing solution and water returning to the general circuit, which means that the solution is everlastingly growing until finally some would have to be run to waste or an enormous storage capacity provided.

Yours faithfully,
GEO. G. THOMAS,
Metallurgist.

## AS IT OCCURRED

To the Editor The Canadian Mining Journal:

Sir,—Dr. Barlow, in his Presidential address, delivered at the Victoria meeting of the Canadian Mining Institute, as reported in the Quarterly Bulletin No. 20, said: "At our last annual meeting there was a rather regrettable occurrence when a mining engineer of repute questioned the value of much of the geological work carried on in Canada." This doubtless refers to the half-brick which his paper on Porcupine stirred me to throwing. Much of the work geologists have done and are doing for the mineral industry and for the mining engineer is splendid. To contend otherwise would be ridiculous. I threw my brick at the posing of certain geologists. My remarks were made entirely on the spur of the moment and are not as carefully worded perhaps as they might be, but they were sound and raised a note not without value. I attach a copy of the "regrettable occurrence" and would ask you to publish it. I am sorry that the publishing committee have not seen fit to publish Dr. Barlow's paper that provoked the remarks.

Yours faithfully,
H. E. T. HAULTAIN.

February 20th, 1913.

Mr. Haultain—I must confess to a growing peevishness, and peevishness is a bad thing to be afflicted with, at the attitude of our local geologists. There are a great many of our local geologists who since they have broken from the Survey——

Mr. Tyrrell—I object to that term, I do not see there is any peevishness whatsoever——

Mr. Haultain—As I was saying, those geologists who have broken loose recently from the Survey, have posed and loomed very largely in the public mind and public eye and in the public press. Their appearance of importance more particularly in regard to the Porcupine district is very very different from their real importportance. Now my experience of the field, fairly limited, has been that an ordinary mining engineer has assimilated sufficient useful geologic knowledge for most of his purposes, and I find that the man who was brought up primarily as a geologist, and goes into the field later, often remains hopelessly geological. This is my peevishness. Now, I will admit, I would be one of the first to admit, that the geologist is of very great importance to the mining interests, as you, sir, so ably showed to us yesterday, but he is not altogether everything up in the Porcupine district. I am particularly glad to see my peevishness accounted for to a certain extent in the result of these two papers by alleged eminent geologists—I say that, sir, alleged eminent geologists. We have been told of three results, as far as I can gather; that the veins go down—I am sure the promoters will seize on that with the greatest of glee. A further thing we were told, and I do not know that it will worry metallurgists very much, is, as we go down the gold will become more refractory—no doubt it will, it has a habit of doing that, and also another to the man up there now.

Now I wish to congratulate our publicity department, for having got off, I believe quite unconsciously, an excellent thing in this morning's "Globe" which strikes me as fitting the case. They refer to a geologist as "An eminent authority on an absolutely unknown region."

# MINING INVESTMENTS

Written by a Mining Accountant.

(Continued from February 1st Issue.)

In the February number of this Journal, when dealing with the matter of sizing up the merits and demerits of mining investments, the writer gave reasons why the acquirement of mining stocks after the payments of dividends thereon generally involves risks far greater than when buying shares in a company at its inception. That this is so and will always remain so in the majority of cases just as long as the present practise of distributing the whole of the surplus income over revenue expenditure in the form of dividends is continued, appear evident. For whereas on the one hand the shares are generally too high to make the ultimate return of capital and a fair rate of interest possible—except in cases when the mine becomes richer at depth—the investment on the other hand offers fair chances of success when due caution is exercised in the manner suggested and when, also, the mine is well investigated and not over capitalized.

The question of inflation or over capitalization, however, is quite another matter and there is no reason why mining companies should not conduct their affairs more in keeping with sound business principles or in such a manner that the shares are never in excess of their actual value.

Under prevailing conditions a company capitalized at $1,000,000 and having, say, an annual income exceeding the revenue expenditure by $400,000, would distribute this so-called profit in the form of dividends.

With this return of 40%, the shares would then in the usual course advance to nearly treble their par value, or until at market price they returned only 15%. This is where the investor is up against inflated values unless, as is very seldom the case, the positive ore reserves, or the conditions generally are such that a similar income is reasonably assured for the next twenty years, as would be necessary for the ultimate replacement of capital and the payment of a rate of interest high enough for mining investments.

On the Transvaal and several other established fields there is some justification for figuring so far ahead of developments. There the ore bodies have been proved to exist at great depth, and the values are so evenly distributed that it is safe to assume that by sinking a certain depth and driving a certain distance within the vertical limits of adjoining properties on the same vein, so much ore having a certain value would be blocked out. On new fields, however, such as Porcupine, the indications at present are certainly not sufficient to justify figuring on any ore for than 100 feet beyond the bottom level and then only when the ore body does not show a falling off in width and value. If tonnage merely is considered this method of determining the life ahead of any Porcupine property for instance, may be considered unduly conservative. But although geologists may agree that the veins must persist to a great depth, there are other points to be considered, such as the falling off in values, shortening of ore shoots, faults, blanks for hundreds of feet as in Bendigo, Australia, (one of the oldest fields in the world) to say nothing of increased working costs and the development of refractory instead of free milling ore as depth is attained. With such contingencies, the possibilities ahead of any Porcupine mine as regards the payment of dividends can only be classed with safety with the "positive" and "probable" ore reserves. In the case of a company such as already instanced, having on the "positive" and "probable" reserves only sufficient ore to maintain the profit of $400,000 per annum for three years, it will readily be seen that there is really no justification for the shares advancing to a price returning only 15% on the investment. Thus the shareholder coming in on such an inflated value is very lucky indeed if he does not clean up minus a large portion of his capital.

This unsatisfactory state of affairs brought about by the common practice of returning capital in the form of enlarged dividends would not exist if mining companies were compelled by law either to create an "Amortization Fund" for the replacement of capital or to notify the shareholder what proportion of the income over revenue expenditure should—guided by the estimated life ahead of the mine—be set aside for the replacement of capital, and how much of this so-called profit should be considered such.

For instance, in the case of a mine as already cited being capitalized at $1,000,000 and having an annual balance of $400,000 over all charges including depreciation and development redemption, and sufficient ore —"positive" and "probable"—to maintain this surplus for three years, we contend for reasons given above that one-quarter of the capitalization at least, that is $250,000, should be set aside for the replacement of capital thus leaving $150,000 for dividends on an annual payment of 15 per cent. On this distribution of the actual profit it will be seen that the shares when returning 10% would show an advance of 50% on the par value thereof. This, then, would be legitimate and those acquiring shares at this valuation would be duly protected against the loss of capital. To bring this about is really the duty of directors and consulting engineers who should, in the writer's opinion, be compelled to give the shareholders the benefit of their experience and of their knowledge of the mine by compulsory semi-annual statements in connection with affairs generally at the mine. They should in fact give a definite idea of what the shares are actually worth after ample provision is made for the replacement of capital and for paying, say 10% interest. The directors or consulting engineers should also be compelled to show how their valuation is arrived at so as to enable shareholders to judge for themselves whether their conclusions are sound.

Out of respect for the powerful arguments which must naturally exist in support of all established methods, the writer would like it to be understood that the object of this article is merely to secure a general expression of opinion as to whether it is possible, or, rather, advisable, to impart a heathier tone to the mining industry by adopting reforms such as suggested herein. In other words, although of the opinion that the present methods are unfavorable to the investor, it is quite possible that the suggested methods for reducing the speculating element in mining to a minimum, may be considered as merely so many flies in an ointment which although undoubtedly injurious to many, may after all be more fit for general use than any other preparation. On the other hand if "amortization funds" are recognized and required by law in other countries, why not in Canada?

(To be continued.)

# TRETHEWEY ANNUAL REPORT.

**Consulting Engineer's Report.**

Toronto, Feb. 6, 1913.

The President and Board of Directors,
Trethewey Silver-Cobalt Mine, Limited,
Toronto, Ontario.

Gentlemen,—Herewith I beg to submit report of operations of the Trethewey Silver-Cobalt Mine, Limited, for the year ending December 31st, 1912.

**Shipments in 1912.**

| | Net Dry Weight Lbs. | Oz. Silver per Ton. | Total Oz. Silver. | Gross Value. | Net. Returns. |
|---|---|---|---|---|---|
| To Orillia | 48,097.0 | 1,010.0 | 24,505.42 | $ 14,341.80 | $ 13,359.14 |
| To Deloro | 859,561.5 | 1,255.5 | 539,605.51 | 331,651.79 | 307,768.46 |
| To Denver A. S. & R. Co. | 234,374 | 237.5 | 27,828.95 | 17,533.78 | 14,105.41 |
| To London (Bullion) | ........ | ...... | 28,983.24 | 18,165.52 | 17,939.17 |
| Totals | 1,142,032.5 | | 620,923.12 | 381,692.89 | 353,172.18 |

### Summary of 1912 Shipments.

| | |
|---|---|
| Total ounces of silver in shipments...... | 620,923.12 |
| Gross value of shipments in 1912 ....... | $381,692.89 |
| Net cash returns from shipments in 1912 | 353,172.18 |
| Aver. price at which silver was paid for | 61.47 per oz |
| Average net cash return, per ounce silver shipped ........................ | 56.89c. |

### Milling.

During the year $8,197.84 was spent on alterations in the mill and charged to operating account. Besides this amount $4,789.02 was spent in additions to building and equipment. The object of alterations and additions was to increase capacity, to reduce the time lost in break-downs of machinery and to ensure a better recovery of silver from the ore. These alterations were made gradually without interfering with the steady production from the mill, and are now practically completed.

### Mining.

Development. The amount expended on development for the year was $50,790.65 for which a total of 3,885.5 lineal feet of development and exploratory work was done, besides 275 cubic yards of sation and grade cutting incidental to development.

### Summary of Development to Date.

| Year | Shafts. | Drifts and Cross-cuts | Winzes and Raises | Tl footage per year | Tl footage to date |
|---|---|---|---|---|---|
| 1906 and 1907 ...................... | 383 | 2,099 | 217 | 2,699 | 2,699 |
| 1908............................. | 0 | 1,711 | 360 | 2,131 | 4,830 |
| 1909............................. | 213 | 2,688 | 268 | 3,169 | 7,999 |
| 1910............................. | 43 | 3,010 | 226 | 3,279 | 11,278 |
| 1911............................. | 102 | 2,801 | 168 | 3,071 | 14,349 |
| 1912............................. | 79 | 2,950 | 856.5 | 3,885.5 | 18,234.5 |

In conenction with the development work a thorough examination of the mine was made during the summer and a system of records started which inventories the "positive" ore at the end of each month. The following table gives a summary of the tonnage of positive ore on hand at the end of each month, dating from August 31st.

### Positive Ore Reserves and Development.

| | | | | | | | | |
|---|---|---|---|---|---|---|---|---|
| Aug. 31 .......... | 4980 | 3757 | 23,784 | 32,521 | 2,246 | .. | 541.5 | .. |
| Sept. 30 .......... | 4866 | 3428 | 22,955 | 31,249 | 2,474 | 1,202 | 543 | 2.21 |
| Oct. 31 .......... | 5278 | 3168 | 22,164 | 30,610 | 2,700 | 2,061 | 603 | 3.42 |
| Nov. 30 .......... | 6422 | 2997 | 21,325 | 30,744 | 2,727 | 2,861 | 436.5 | 6.55 |
| Dec. 31 .......... | 6413 | 3825 | 20,934 | 31,172 | 2,284 | 2,712 | 409.5 | 6.62 |

As shown by the foregoing table, the balance between new ore developed and the ore extracted has held up fairly well during the last four months of the year for which figures are available.

The average rate at which development work placed new ore in sight during the last four months was 2,209 tons per month.

The greater part of the development work was done in the south-east quarter of the property that is tributary to No. 2 and No. 5 shafts. This work has continued to yield good results and several small veins were found which gave a good grade of milling ore. In other cases the extensions or parallel branches of older veins were discovered, the working of which was very profitable.

The No. 6 shaft was sunk to the second level and some exploratory work done on the east central portion of the property in conglomerate. While a strong vein with a calcite filling exists at this point, the work done on it has so far not yielded any ore.

With the exception of a small amount of cross-cutting done during the first three months of the year, no development work was done in the north-east section of the property from No. 4 shaft. There are three veins in this section close to the T. & H. B. Co.'s boundary, and, while no 'positive' ore reserves from this section are included in the estimates, some exposures of good veins exist in pillars left in the old stopes, and the chances of finding other veins are favorable.

Ore Reserves.—The total amount of "positive" ore in sight in the mine, blocked out, at the end of 1912 was 6,413 tons with an average silver content of about 28 ounces per ton. In addition to this there were 3,825 tons of ore broken in the stopes averaging about 26 ounces per ton, and 20,934 tons of broken ore on the surface dumps averaging 15 ounces per ton, all of which may be considered "positive" ore.

In the above estimate of Ore Reserves no allowance has been made for ore not thoroughly blocked out, nor for ore on dumps not sampled and measured.

A change of management was made in the middle of the year which involved numerous changes in the personnel of the staff at the mine. Considerable credit is due Mr. H. G. Young, who has done excellent work since his appointment as manager.

I have pleasure in submitting herewith Mr. Young's report.

Yours very truly,
D. L. H. FORBES,
Consulting Engineer.

---

### Manager's Report.

Trethewey Silver-Cobalt Mine, Limited,
Mine Office, Cobalt, Ont.,
February 4, 1913

Mr. D. L. H. Forbes, Consulting Engineer,
Trethewey Silver-Cobalt Mine, Ltd.,
306 Manning Chambers,
Toronto.

Dear Sir,—I beg to submit the following report of operations at the Trethewey Mine for the year ending December 31st, 1912:

### Development.

During the year $50,790.65 was spent on development, and 3,885.5 lineal feet of work was accomplished, made up as follows:

| | Feet |
|---|---|
| Drifting | 2072.5 |
| Cross-cuts | 877.5 |
| Raises | 788.5 |
| Winzes | 68.0 |
| Sinking | 79.0 |
| Total | 3885.5 |

In the cast of this work is included 250 cubic yards of station cutting and 25 cubic yards of grading.

### (1) S.W. Section, Near No. 5 Shaft.

(A) First Level.—In this section the north branch of "D" vein was picked up, and an ore chute developed 75 feet in length and about 40 feet vertically. The vein is one to two inches wide of high grade ore, and the wall rock carries good milling values. Some stoping was done during the year on this vein, which gave us excellent ore.

(B) Second Level.—In this section the "D" vein was developed by a winze below the first level to the Keewatin-Conglomerate contact and drifted on for a length of about 60 feet. This work gave us an excellent grade of ore. The vein is one to two inches wide.

"H" vein. This vein was developed by raises from the second sub-level. It is two to three inches wide of medium ore. The ore chute developed was about 60 feet long and 40 feet in depth. Considerable stoping was done here during the year, with good results.

### (2) East Section, Near No. 2 Shaft.

(A) First Level.—The continuation of main vein was picked up west of "S" vein, and developed for a length of about 140 feet and 30 feet vertically. We obtained from this work a very good grade of milling ore on which no stoping has been done as yet. A parallel vein called "G" vein, which joins the main vein, was opened up for a length of 60 feet and 30 feet vertically. This gave us a very good grade of milling ore, which still remains intact.

"E" vein, parallel to "S"—This vein was drifted on for 80 feet, and a raise put up about 40 feet. The ore was very good. No stoping was done here.

"S" Vein.—A small amount of milling ore was developed on this vein above the first level by a series of raises.

No. 1 vein south, off main vein and Nos. 2 and 3 to the north of main vein were developed, and gave us a good grade of milling ore from small ore chutes.

(B) Second Level.—On this level vein No. 151 was picked up from a cross-cut. A small amount of development was done on it by a raise to the first level, a distance of about 40 feet. The vein is about an inch wide of high grade ore, and development to date looks very promising.

South Extension of No. 10 ein.—This vein, although small, gave us an excellent milling ore in the development done on it. The ore chute is about 50 feet long and 30 feet vertically.

### (3) Central Section.

No. 6 Shaft.—This shaft was sunk during the year to the second level, and approximately 450 feet of drifting was accomplished on the "mill fissure" vein, 100 feet of which was one on the first level and 350 feet on the second level. This vein is a wide calcite vein which at first gave promise of producing ore, but developments proved disappointing. We also did about 225 feet of cross-cutting from this vein to the south and found nothing.

### (4) North Section.

Considerable cross-cutting was done in the early part of the year on the second level to the south in No. 4 shaft workings. No veins were encountered. No work has been done in this section during the last nine months. However, this section gives promise of producing considerably more ore.

### Acreage.

The Trethewey Mine consists of approximately 40 acres of which is made up of Keewatin formation and very shallow conglomerate, in which no values have been found. The remaining twenty-five acres is composed of conglomerate. About 12.5 acres of this productive conglomerate formation has been developed. The remaining 12½ acres is so far unexplored.

### Compensation to Miners.

During the last six months we have introduced the contract system of labour as far as possible. This has given us very good results. We find that the miners make more money, and take more interest in the work and are more contented, while the company on the whole gets cheaper work done and better results.

### Boarding Camp.

In October we closed down the boarding camps. We found it very difficult to operate these without a constant loss of $300 or $400 per month to the company. They also necessitated a great deal of attention from the office in order to run them economically. Our proximity to the town enabled us to do this without any great inconvenience to the miners, and we find the present arrangement much more satisfactory to all concerned.

### Accidents.

I regret very much to report to you the large number of accidents which have occurred on this property during the last year. Fourteen were minor accidents which might have happened in almost any operation. However, a number of them were more serious and one fatal. Twenty accidents occurred altogether. It is the constant endeavour of the management to reduce these to a minimum.

### Changes in the Mill.

During the last six months it was found necessary to make a number of additions and changes to the mill plant. During October and November we installed a complete return heating system, which is working out very economically. Our consumption of coal for heating the mill and drying concentrates is about a ton per day. We also built a new dry house for drying and storing mill concentrates. We also erected a tailings stacker in order to pile up our mill tailings and hold them on the property. At present we are altering the rock crushing plant in order to make it more economical of operation and to do better crushing, which will help out our mill tonnage.

I wish to thank the staff and employees for their willing and hearty co-operation with the management towards obtaining good results.

Yours truly,
H. G. YOUNG,
Manager.

# OCCURRENCE, DISTRIBUTION AND UTILIZATION OF BISMUTH ORES*

## BISMUTH MINERALS.

Bismuth minerals are not of very frequent occurrence, and they are usually found only in small quantities. The localities at which they are found in sufficient abundance to constitute workable ores of bismuth are few, and they rarely if ever occur in such a degree of purity that they can be worked for bismuth alone, the bismuth usually being one of several products obtained.

The minerals of chief importance as constituents of workable bismuth ores are native bismuth and bismuthinite. Bismite and bismutite also occur in considerable quantities. Other minerals containing a high percentage of bismuth are bismutosphaerite (carbonate) ,pucherite (bismuth vanadate), uranosphaerite (bismuth uranate), guanajuatite (bismuth selenide), tetradymite (bismuth telluride) as well as a considerable number of double sulphides containing lead, copper or silver. Bismuth also occurs as a natural alloy with gold, the composition of which corresponds to the formula $Au_2Bi$, as in maldonite, found at Maldon, Victoria, Australia. It also occurs alloyed with silver in chilenite, found in the San Antonio mines, Potrero Grande, in Copiapo, Chile. These minerals, however, so far as is known at present, are comparatively rare and of no economic importance as constituents of bismuth ore.

The following is a brief description of the more important ore-minerals of bismuth referred to above:

Native bismuth is a greyish-black heavy mineral the freshly fractured surface of which shows a white metallic lustre with a somewhat pinkish tinge. It is usually found in lamellar or granular masses, and is very brittle and sectile. Its specific gravity varies from 9.6 to 9.8. Native bismuth occasionally contains traces of other elements, notably arsenic, sulphur, and tellurium.

Bismuthinite, or bismuth glance, bismuth sulphide ($Bi_2S_3$), is a lead-grey brittle mineral, having a specific gravity of about 6.5, a hardness of 2, and a grey streak. It crystallizes in the orthorhombic system, is readily fusible and sectile, and often occurs associated with other bismuth ores, particularly the native metal. It contains about 81 per cent. of bismuth.

Bismite, or bismuth ochre ($Bi_2O_3$), occurs in massive form and is occasionally foliated. It varies in color from grey to yellowish-white, and has a specific gravity about 4.4. It contains about 90 per cent. of bismuth.

Bismutite is a hydrated bismuth carbonate. It is soft and easily crushed, and ranges in colour from white to yellow. The specific gravity varies from about 7.0 to 7.5 and hardness from 4 to 4.5. The mineral contains about 90 per cent. of bismuth.

Bismutosphaerite is a bismuth carbonate containing little or no water. It occurs in spherical forms with concentric and radiating structure. In colour it varies from bright yellow to dark grey or dark brown, has a hardness 3 to 3.5 and a specific gravity about 7.3 to 7.6. It contains about 90 per cent. of bismuth.

Although the chief bismuth minerals contain high percentages of the metal, the ores as mined seldom contain more than about 10 or 20 per cent.

Bismuth ores sometimes occur in the quartz and pegmatite veins traversing gneisses, granites, porphyries, and slates, and also in a disseminated form in these rocks. The minerals other than those of bismuth most frequently found in bismuth ores are galena, zinc blende, iron and copper pyrites, sulphides of cobalt and nickel, barytes, cassiterite, wolframite, scheelite, molybdenite, and haematite. Antimony, gold, and silver minerals also occur.

## DISTRIBUTION OF BISMUTH ORES.

### Europe.

**United Kingdom.**—This country does not figure in the official returns as a producer of bismuth ores, but occurrences have been reported from several localities. Native bismuth occurs at the Wheal Sparnon mine, Cornwall, in a rich vein at the Atlas mine in Devonshire, and at Carrock Fells, Cumberland. At the last-mentioned locality bismuth sulphide also occurs in quartz, associated with molybdenite and apatite; it is also found in Cornwall at the Botallack mine, near Redruth, at the Lanescott mine near St. Austell, and at the Hedland mine, Gwennap. Bismite occurs at St. Roach and near Lostwithiel, Cornwall. At one time bismuth ores, which occur with copper ore, spathic iron ore an diron pyrites, were obtained from the Fowey Consols mine, near Tywardreath, Cornwall.

**France.**—For some years bismuth ores were obtained at Meymac from a vein in the granite, which gave chiefly wolframite and arsenical pyrites near the surface and increasing quantities of bismuth in depth. The percentage composition of a sample of the native bismuth from this locality is as follows: bismuth 99.00, antimony 0.15, arsenic 0.09, lead 0.41, iron 0.1, sulphur 0.06.

**Austria-Hungary.**—Bismuth ores occur and have been worked in Bohemia, Carinthia, and near Salzburg. Bismuth telluride occurs in the Banat at Cziklova and in the gold and silver mines of Rezanya, Small quantities are won from the Joachimsthal uranium ores.

**Germany.**—In the past, bismuth ores have been obtained from many localities in Germany and for many years the greater part of the world's output was obtained from Saxony. One of the most important deposits in the latter State is that of Schneeberg, which consists of large masses of granite surrounded by mica schists and clay slates, the mineralized veins usually being found in the latter. A variety of lodes occur; the bismuth ores are generally found in the cobalt veins, which are numerous, and contain quartz, hornstone, cobaltine, native bismuth, pyrites, galena, pyrargyrite, native silver, and other minerals. At Altenberg bismuth glance and native bismuth occur in quartz veins which traverse the "zwitter," a dark-coloured rock composed of quartz and mica, and containing a small quantity of finely divided tinstone. The bismuth ores are associated with iron and copper pyrites, wolframite, molybdenite, fluorite, and other minerals.

In the neighbourhood of Johanngeorgenstadt ores of bismuth are found along with those of silver and cobalt, in the vicinity of the metalliferous greenstones, which traverse the granite.

### Australian Commonwealth.

**Victoria.**—Bismuth ores are stated to be found in some quantity among the deposits of Wombat and

*A paper published in the Bulletin of the Imperial Institute.

Snowy Creeks, in the north-eastern district of Victoria. The ores also occur in reefs at Moliagul and Kingower, in Gladstone; Linton, in Grenville; St. Arnaud and Maldon (The Economic Minerals and Rocks of Victoria. A. E. Kitson, Melbourne: Victoria Department of Mines, 1906). During 1910 deposits were discovered at Round Hill, Bendoc, in East Gippsland, containing wolframite and bismuth ore in payable quantities, and several small parcels of ore were marketed. The prospects are said to be encouraging, but further development work will be necessary in order to determine the value of the deposit (Ann. Rep. Sec. Mines, Victoria 1910, pp. 26, 131).

**New South Wales.**—Bismuth and its ores have been found in many places in this State, but the production during recent years has practically all taken place from two localities: Kingsgate, near Glen Innes, and Whipstick, near Panbula. During the period 1880 to 1910, 527 tons of bismuth ore, valued at £125,527, were exported from New South Wales. The Kingsgate deposits are situated at Yarrow Creek, about eighteen miles east of Glen Innes. Geologically, the country consists of granites and indurated claystones of Carboniferous age. The bismuth deposits are found in nearly circular pipe-veins, which occur near the junction of the granite and claystones and dip in an easterly or north-easterly direction at an angle of about 30°. These pipe-veins vary from 10 ft. to 50 ft. in diameter, several often uniting as they are traced downwards. The gangue in the pipes consists of quartz, containing molybdenite in large crystals and occasionally wolframite and mispickel. Gold and silver are usually present in variable amounts. Near the surface the bismuth ore, which is less plentiful than the molybdenite, occurs as the oxide and carbonate in the joint fissures of the quartz. At greater depths native bismuth and the sulphide are found.

The pipe-veins contain from 0.5 to 5.0 per cent. of bismuth. An average sample of the ore-stuff yielded: metallic bismuth, 2.6 per cent.; gold, 8 dwts. per ton; silver, 3 oz. 5 dwts. per ton. The concentrated ore had the following composition: metallic bismuth, 69.3 per cent.; gold, 4 oz. 1.5 dwt. per ton; silver, 57 oz. 3 dwt. per ton.

The Whipstick deposits, situated about fourteen miles west of Panbula, at one time produced nearly all the bismuth ore obtained in New South Wales. The deposits are very similar in character to those of Kingsgate described above, except that the filling of the pipes here consists of quartz and felspar, with a little mica and some garnet rock. Wolframite is generally absent.

The ore, after being roughly hand-picked, contains on an average 4 per cent. of bismuth and is sent to Sydney for concentration and reduction, the wet process, described later, being usually employed for the latter purpose. Bismuth ores have been found in many other localities in this State. For an account of these see Mineral Resources of New South Wales, by E. F. Pittman. (Sydney: W. A. Gullick, 1901).

**Queensland.**—For many years past this State has produced varying quantities of bismuth ore. Recently the chief producing area has been the Biggenden district, where bismuth occurs associated with magnetic iron ore. Other producing deposits occur in the Herberton and Chillagoe districts, and small quantities are occasionally obtained in the Etheridge and Star River districts. An occurrence in the Degilbo district has been worked to some extent. The lode, which is 3 ft. wide, is said to outcrop in a position favourable for working. The ore consists of bismuth carbonate, sulphide and telluride, and contains varying amounts of gold, silver and copper, and occurs in fissures. The country rock is an altered slate intersected by porphyry dykes. A sample of the picked ore contained 3.6 per cent. bismuth, 12.1 per cent. copper, and 5 oz. of silver per ton. The Glen bismuth mines of the Herberton district have already been referred to in this Bulletin (1912, 10, 330).

**South Australia.**—Although during the period 1867 to 1876 about 71 tons of bismuth ore, valued at £16,679, were obtained from South Australia, no production was recorded from 1876 to 1906; and during recent years the quantity raised has been insignificant. Bismuth ore, in the form of sulphide, carbonate, oxide, and native metal, has been found in at least 18 mines in this State. An account of these occurrences, together with a record of the amount of development work done, which in some cases has been considerable, will be found in the Record of Mines of South Australia, by H. Y. L. Brown (Adelaide: C. E. Bristow, 1908).

**Tasmania.**—There is a small but steadily increasing production of bismuth ore from Tasmania, the output during recent years being almost entirely obtained from the Shepherd and Murphy mine in the Middlesex district. The ore here occurs in quartz-topaz veins in a metamorphic limestone, together with wolframite and cassiterite. It also occurs at other mines in this district. Bismuth ore has also been located at Mount Black in quartz, associated with gold, wolframite, and other minerals. A sample of the ore contained 7.4 per cent. bismuth, 0.8 per cent. copper, and 0.95 oz. of gold per ton.

In the Heemskirk Mountains bismuth is said to occur in lodes with tin and silver, and near Ringville a number of lodes have been worked yielding rich argentiferous bismuthic fahl ores.

### Asia.

**India.**—Very few occurrences of bismuth ore have been recorded in India. Bismutite is said to occur with antimony ore in the range of hills between the Attaran and Maulmain rivers, Tenasserim. Bismuth also occurs in small amounts, with the copper ores of Hazaribagh and Singhbhoum, Bengal, whilst certain ores from Nepal carry 24 per cent. of bismuth and 14 per cent. of copper. The copper ores from the Mundi State, Punjab, are also said to contain bismuth (S. C. Rudra, Trans. Amer. Inst. Min. Eng., 1903, 34, 81).

**Japan.**—At one time bismuth was extracted from the ores of Nishizawa district, Hida, and small quantities of ore are produced from mines in Rikuchu and Mimasaka. The ore is known to occur in many other localities, a full list of which will be found in Mining in Japan (Tokio Bureau of Mines, 1909).

**Sumatra.**—Bismuth ore is stated to occur in commercial quantities near Lake Toba.

### Africa.

**Rhodesia.**—All the commoner ores of bismuth enumerated on pp. 628, 629 have been recorded from Rhodesia, the chief localities being Mazoe and Lomagundi. Bismuthinite occurs as an impregnation together with molybdenite and pyrrhotite disseminated through syenite at the Hay mine, Mazoe. The ore is worked for its gold, but the bismuth does not appear to be recovered.

Bismutite has been found in notable quantity in gold-bearing quartz veins at Victoria and Lomagundi. Native bismuth occurs in the Hartley district and bismuth ochre at Gadzema.

**Transvaal.**—Bismuth telluride is said to occur about twenty miles north-east of Pretoria and bismite in the auriferous deposits of the Lydenburg district.

**German South-West Africa.**—Native bismuth is found mover a large area in the Knisib district of Damaraland, in quartz veins which traverse a mica schist. The metal is often accompanied by bismuth ochre, and by gold, silver, and copper ores.

### America.

**Canada.**—Native bismuth is said to be of fairly common occurrence in the sluice-boxes of the alluvial gold workings of Highet Creek, a tributary of the Stewart River, Yukon. The same mineral also occurs in quartz veins with smaltite, in the Montreal River district. Bismutite occurs at New Ross, Lunenburg county together with ores of tin, tungsten, and molybdenum in pegmatite and aplite dykes. The mineral also occurs in quartz veins in an altered granite near Kewagama Lake, Quebec; also near Lyndock and at Clarendon, Ontario.

**United States.**—Only during the last few years has bismuth been produced in the United States, and at the present time there is very little bismuth ore raised as such, the bulk of the bismuth obtained being recovered from the refining of other metals. Amongst these sources may be mentioned the anode slimes from the electrolytic refining of copper at Chrome, New Jersey, and the Betts electrolytic lead process worked at Grasselli, Indiana, where the lead ores from the Tintic district are smelted. At Leadville, Colorado, ores carrying 7 to 14 per cent. of bismuth have been obtained. Deposits near Mesa and Phoenix, in Arizona, have been developed to some extent. Small shipments containing 11 to 25 per cent. of bismuth have been made from San Andreas Mountain section, New Mexico.

**Mexico.**—High-grade bismuth ore has been obtained from Sinaloa and Sonora. The Rey del Bismuto mine in Sinaloa yields a large quantity of ore containing bismuth 2 per cent., iron 33, silica 31, copper 0.9, and alumina 12.5. A smelting trial gave 80 to 90 per cent. of the theoretical yield of bismuth. Rich oxidized ores have been obtained near Ojo Caliente, Chihuahua. Bismuth ochre occurs in the nickel-cobalt deposits in Jalisco.

**Brazil.**—In Entre Rios, Minas Geraes, deposits of metallic bismuth have been located. The ore is stated to carry less than 7 per cent. of impurity.

**Peru.**—Deposits have been worked near San Gregorio, Cerro del Pasco. In San Mateo, Lima, the mineral chiviatite, a sulphide of lead and bismuth, has been found; and it also occurs with bismuthinite in Yauli, Lima, and Juaja, Junin.

**Bolivia.**—At the present time a large proportion of the bismuth ore produced is obtained from Bolivia. The most important deposits are situated at Tasna, where the ores, which include the native metal, carbonate, sulphide and ochre, are said to carry from 20 to 30 per cent. of bismuth, 10 to 17 per cent. of iron, 9 to 12 per cent. of sulphur, and traces of antimony, silver, and lead. The ores occur in quartz veins in slates at an altitude of 5,100 ft. The ore is smelted at Quechisla, the products being metallic bismuth and a copper matte carrying 5 to 8 per cent. of bismuth. The matte is re-smelted and about half the bismuth contained in it is recovered. The second matte is treated by the "wet process" described later.

### Dressing of Bismuth Ores.

At first sight it would appear that the concentration of bismuth ores, owing to their high specific gravity, should present few difficulties. Owing, however, to the extreme brittleness of the minerals, they form slimes very readily when crushed, and so considerable loss occurs during dressing. The finely powdered mineral, even if saved by suitable slime treatment, is objectionable, as losses occur by "dusting" and also during calcination by reason of the ready volatility of bismuth. These difficulties, combined with the fact that many bismuth mines are only operated on a small scale, have caused the question of the effective concentration of bismuth ores to be much neglected. Recently more attention has been paid to the subject, and magnetic separation has been successfully employed in some cases as in the separation of wolframite.

A method of concentration formerly employed for ores containing native bismuth, or the sulphide, is that of liquation; but, owing to the losses involved in the process, it is now not often used. The process consists in heating the ore in inclined iron tubes closed at the top end, the lower end being fitted with a grating and arranged to deliver the molten matter into a graphite crucible containing a layer of carbon. The method of concentration sometimes employed in New South Wales is as follows: After being hand-picked the ore is crushed to ¼-inch size, and then treated in a sluice-box having a fall of 9 in. in 12 ft., being worked meanwhile with a shovel and birch broom. By this means a concentrate carrying 20 per cent. of bismuth is obtained which is treated again in a similar sluice-box, and, after removal of the larger pieces of molybdenite by hand, a product containing 50 to 60 per cent. of bismuth is obtained.

According to the Annual Report of the Minister of Mines for Queensland (1909, p. 95) the mill in operation in the Biggenden district (see this article) consists of a stonebreaker, sizer, and two 5-foot Huntington mills and the concentration plant of two Frue vanners, 1 card, and 2 Wilfley tables and an electromagnetic separator.

### Extraction of Metallic Bismuth.

The concentrated ore is usually submitted for the extraction of the metal to one or all of a series of operations, which may be roughly divided into roasting, smelting and refining.

Roasting.—The ores containing arsenic, sulphur, or antimony, before being smelted, are crushed to pass a sieve having four meshes to the linear inch and then roasted with carbon. As neither "heap" nor "kiln" roasting is suitable for bismuth ores, the operation is best carried out in a long hearth, reverberatory furnace; a furnace having a hearth 16 ft. by 9 ft. is suitable for treating about six to seven tons of material per day. The charge is subjected during heating to constant rabbling to prevent the mass agglomerating and to assist the volatilization of the arsenic and antimony.

Smelting.—This is done either in crucibles or in a reverberatory furnace, the latter being the more economical unless small scale operations are intended. Descriptions and plans of suitable furnaces will be found in an article in The Mineral Industry (1907, 16, 112). Owing to the readily volatile character of bismuth the charge must be of a very fusible character, and usually contains 10 to 20 per cent. of sodium carbonate, together with oxide of iron, lime, and old slags in suitable proportions, and 3 to 5 per cent. of crushed coke or charcoal. The charge in the furnace is raised to a red heat, and when the bismuth is reduced the temperature is rapidly raised to a white heat. As soon as the contents of the furnace are quite fluid the charge is run into iron moulds, which are often provided with a taphole at the bottom to permit of the still liquid bismuth being run off as soon as the top slag has solidified. This crude bismuth contains most of the lead, gold, silver, and antimony, and a small proportion of the arsenic and copper which were present in the original charge. The copper, for the most part forms a matte, whilst the nickel and cobalt form a speiss with part of the arsenic. Both the speiss and matte contain appreciable quantities of bismuth.

Several "wet" processes of extraction have been employed for the treatment of oxidized bismuth ores. One which was used at Meymac, France, for a number of years is as follows: The finely crushed ore is heated in earthenware pans with strong hydrochloric acid and the solution filtered from the insoluble gangue. By diluting this solution with a large excess of water the bismuth is precipitated as the oxychloride, which can be converted into the metal by treatment with iron or zinc. The method now usually employed at Meymac is to precipitate the bismuth from the acid solution by means of metallic iron and then melt the precipitated bismuth in a plumbago crucible under a layer of carbon.

Refining.—The crude bismuth produced by any of the above processes is not usually sufficiently pure to place on the market. Owing to the small affinity that bismuth has for oxygen, a process similar to that employed for refining lead is used. The molten bismuth is exposed for some time to the influence of atmospheric oxygen, which causes any tin, arsenic, antimony, sulphur, zinc, iron, etc., to be either volatilized or separated as "dross."

The percentage composition of crude and refined bismuth as produced in some of the most important centres is shown in the following table.

| | Crude Bismuth. | | | Refined Bismuth. | |
|---|---|---|---|---|---|
| | Australia. | Bolivia. | Peru. | Saxony. | |
| Bismuth. . . . . | 96.2 | 99.05 | 93.57 | 99.74 | 99.98 |
| Antimony. . . . . | 0.8 | 0.56 | 4.57 | — | — |
| Arsenic. . . . . . | trace | — | — | 0.01 | trace |
| Copper. . . . . . . | 0.5 | 0.26 | 2.06 | 0.02 | 0.03 |
| Lead. . . . . . . . | 2.1 | — | — | 0.11 | 0.06 |
| Iron. . . . . . . . . | 0.4 | — | — | trace | trace |
| Sulphur. . . . . . | — | — | — | 0.04 | — |
| Silver. . . . . . . . | — | 0.08 | — | 0.07 | — |

## Properties and Uses of Bismuth.

Bismuth is a silver white, lustrous metal, having a specific gravity 9.83 and melting at 270°C. In appearance it somewhat resembles antimony, but has a foliated texture.

Molten bismuth, on cooling, expands about 2.3 per cent. of its volume, a property which makes it of value in alloys used for the production of stereotype plates. The molten metal can be cooled 6°C below its solidifying point and still remain liquid, but when solidification occurs it is accompanied by a rise in temperature. The metal is not affected by dry air, but in the presence of moisture it becomes coated with a reddish powder. When raised to a red heat in air it burns with a bluish flame producing the yellow oxide, $Bi_2O_3$. Metallic bismuth has a very low thermal conductivity compared with silver, the ratio of the two being 1.8:100. Owing to its low melting-point, the metal is much used in fusible alloys; the composition of certain of these is given in the following table:

| Name of alloy. | Melting point | Percentage composition Bismuth. | Tin. | Cadmium. | Lead |
|---|---|---|---|---|---|
| Rose's. . . . . | 94°C. | 50 | 25 | — | 25 |
| Wood's. . . | 66°C.-70°C. | 50 | 14 | 12 | 24 |
| Lipowitz'. . . | 60°C. | 50 | 13 | 10 | 27 |
| Newton's. . . | 94°C. | 20 | 30 | — | 50 |

These figures show that the replacement of a portion of the tin by cadmium considerably lowers the melting point of the alloy.

An amalgam of bismuth and mercury with or without the addition of lead and tin is stated to be sometimes used for silvering mirrors.

A small quantity of bismuth, not exceeding 0.25 per cent., is a component of many anti-friction metals. Certain electric fuses have the composition: bismuth 50, cadium 15, lead 20, tin 21 parts. A solder used by pewterers consists of bismuth 25 per cent., tin 50 per cent., and lead 25 per cent.

Stereotype plates often contain bismuth; in one case the percentage composition is as follows: bismuth 15, lead 70, antimony 15.

Bismuth oxide ($Bi_2O_3$) has been used as one of the constituents of optical glass, and also for colouring porcelain and other purposes.

The basic subnitrate (oxynitrate) was at one time used as a cosmetic, but is now largely displaced by the cheaper zinc white.

Bismuth compounds also find considerable employment in medicine, the chief of these being the oxide, oxycarbonate, oxynitrate, and salicylate.

## Commercial Value of Bismuth Ores.

Owing to the fact that the principal European bismuth smelters are members of an association which regulates the price and output of the metal, there is practically no competition amongst buyers, and the market is very restricted.

Ores containing less than 10 per cent. of bismuth are not usually saleable. As is usually the case with metallic ores, those containing a high percentage of the metal realize a higher price per unit than those of lower grades. No definite information can be given as to the value of bismuth ores, but the following statement, based on data given in The Mineral Industry (1907, 16, 118), may be of service in affording approximate estimates of value.

If the value of an ore containing 10 per cent. of bismuth is taken as unity, the value of a 15-per-cent. ore would be 1.7, a 20-per-cent. ore 2.3, a 30-per-cent. ore 3.7, a 40-per-cent. ore 5.0, and a 50-per-cent. ore 6.7. With metallic bismuth at 6s. 8d. per lb., the value of a unit varies from £18 15s. to £20 16s., e.g., an ore carrying 15 per cent. of bismuth would be worth £31 17s. 6d. to £35 7s. per ton. These prices are c.i.f. smelting works. Gold and silver in the ore is either not paid for at full rates or a treatment charge is made.

Other constituents present in the ore may also influence its selling value. Copper, iron, and arsenic are stated to be objectionable (Mineral Industry, 1909, 18, 74). Up to 10 per cent. of copper is permitted in an ore carrying 25 per cent. of bismuth, and up to 2 per cent. in ores carrying 6 per cent. or less of bismuth. Up to 10 per cent. of iron is permitted; arsenic must not exceed 12 per cent.

Early in 1905 the price of bismuth was 9s. per lb., but during the year it was reduced to 5s.; in 1907-9 the price was 6s. 6d.; the current value is 7s. 6d. per lb.

#### Production of Bismuth Ores.

Statistics of production of bismuth ores in recent years, so far as they are available, are given in the following table:

Specimens of bismuth ores from the following localities in the British Empire are shown in the Public Exhibition Galleries of the Imperial Institute.

Queensland—Erin Mine, Eidswold; Cloncurry; Mount Biggenden; Chowney Creek; Kaboonga, near Kilkivan; Mount Shamrock, Maryborough.

New South Wales.—Mount Gipps, Barrier Range; Jingera, Co. Auckland; Kingsgate, New England.

Tasmania.—Middlesex district.

# THE ANNUAL MEETING OF THE CANADIAN MINING INSTITUTE

The final programme for the Annual Meeting of the Institute, which will be held in Ottawa on March 5th, 6th, and 7th, next, is as follows:

#### Wednesday Morning.

The meeting will be opened at 11.00 p.m. by H.R.H. the Governor-General. The President, Dr. A. E. Barlow, will then deliver an address. This will be followed by the consideration of proposed amendments to the By-laws; and by the presentation of mineral statistics for the year 1912 by Mr. John McLeish, of the Mines Branch of the Department of Mines, Ottawa; by Mr. T. W. Gibson, Deputy Minister of Mines of Ontario; by Mr. T. Denis, Superintendent of Mines of Quebec; and by Mr. W. Fleet Robertson, Provincial Mineralogist of British Columbia.

#### Wednesday Afternoon.

At this session the papers will be mainly relative to mining industries in the vicinity of Ottawa, and will include the following: "Mica Mining in Canada," by Hugh de Schmid, Ottawa; "Mica Manufacture and Marketing," by S. O. Fillion, Ottawa; "The Origin of Graphite," by John Stansfield, McGill University, Montreal. These papers will be followed by a short lecture by Mr. J. J. Penhale, of Sherbrooke, on "The Evolution of Mining and Milling Asbestos in the Eastern Townships of Quebec."

#### Wednesday Evening.

On Wednesday evening Dr. Henry M. Payne, of New York will lecture on "The Development and Problem of the Yukon." The chair at this session will be occupied by Dr. Alfred M. Thompson, M.P., of Dawson, Y.T., who will introduce the lecturer, and also deliver an address on "The Progress of Mining in the Yukon."

#### Thursday Morning.

The papers at this session will relate more particularly to the metallurgy of the gold and silver ores of the Porcupine and Cobalt districts, respectively. They include: "Cyanide Practise in Canada," by Herbert A. Megraw, New York; "The Metallurgy of the Porcupine Gold Ores," by D. L. H. Forbes, Toronto; "Grading Analyses, and Their Application to Cyanidation, Classification, etc.," by John W. Bell, McGill University, Montreal; "The Measurement of Compressed Air Delivered by the Hydraulic Compressor at Cobalt," by C. H. Taylor, Toronto, and "Notes on Mine Sampling," by G. C. Bateman, Toronto.

#### Thursday Afternoon.

All the papers to be presented at this session will deal with iron mining or metallurgy. They include the following: "Aglomeration of Iron Ores," by N. V. Hansell, New York; "Prospecting the Iron Sands of Natashkwan, Quebec, with the Empire Drill," by G. C.

Mackenzie, Mines Branch, Department of Mines, Ottawa; "The Steel Industry of Nova Scotia," by Thos. Cantley, New Glasgow, N. S.; and "Iron Mining in Cuba," by Chas. F. Rand, New York.

### Thursday Evening.

In keeping with tradition, Thursday evening has been set apart for the annual smoking concert. The programme has been arranged entirely by a local committee, who, while refusing to divulge details, have given assurances that the entertainment will eclipse all former efforts in this direction.

### Friday Morning.

The following papers will be presented: "Recent Advances in our Knowledge of the Sudbury Region," by A. P. Coleman, Toronto; "Money Metal," by Wm. Campbell, New York; "Magmatic Origin of the Sudbury Nickel Copper Deposits," by Reginald E. Hore, Houghton, Mich.; "Some Notes on the Pearl Lake Section of the Porcupine District," by H. G. Skavlem, Aura Lake, Ont.; "Investigations of the United States Bureau of Mines in Metal Mines," by George S. Rice, Pittsburg, Pa.; "State Aid to Mining in Australasia," by H. Mortimer-Lamb, Montreal.

### Friday Afternoon.

"The Clay Deposits of Western Canada," by Heinrich Ries, Ithaca, N.Y.; "Core Drilling," by P. H. Moore, Toronto; "An Economic Investigation of the Coals of Canada," by J. B. Porter, McGill University, Montreal; "The Lignites of Saskatchewan," by R. O. Wynne Roberts, Regina, Sask.; "Prospecting and Washing for Diamonds," by W. J. Dick, Ottawa; "Recent Metallurgical Developments," by Alfred Stansfield, McGill University, Montreal; "The Pulmotor in Mine Rescue Work," by Henry E. Bertling, Toronto.

### Friday Evening.

The annual dinner will be held at 7.30 p.m. The feature this year will be that music is substituted for the usual long toast list, the only speaker of the evening being the Right Hon. R. L. Borden, who will be the guest of honor.

# WHY THE NICKLE PLATE MINE WAS SOLD

By E. Jacobs, Victoria, B.C.

When in Spokane, Washington, last November, I had a talk with Mr. F. A. Ross, formerly general manager for the executors of the late Marcus Daly, of the Nickel Plate group of gold mines, in Hedley camp, Similkameen, and the 40-stamp mill at Hedley, relative to the sale of that property to the syndicate that organized the present Hedley Gold Mining Co. Reflections on Mr. Ross' management of the mines and statements concerning the sale of the property by the Daly interests having been publicly made, I was desirous of hearing the other side of the story. Immediately after my return to Victoria I had to give all my time and attention to the work of preparing the several annual reviews of mining in British Columbia, since published in half a dozen influential mining journals, so had to defer for the time putting in shape for publication what Mr. Ross told me of the circumstances that led to the sale of the property. Quite recently, however, I received a copy of the Northwest Mining News, edited by Mr. L. K. Armstrong of Spokane, and in that journal found printed a copy of a paper on "The Microscope in Mining Geology," by Mr. C. A. Stewart, professor of geology, at the Idaho State University, Moscow, Idaho, and discussion by Mr. Ross of that paper, at the time it was read before the Spokane Local Section of the American Institute of Mining Engineers. I shall not now give a synopsis of Professor Stewart's paper, but shall quote only Mr. Ross' comments, as follows:

"Professor Stewart's paper is timely and to the point. With the passing years we grow more dependent upon practical applications of the principles of economic geology in the search for new ore bodies and too much emphasis, therefore, cannot be placed upon the importance of that science and of all that relates thereto. From Yucatan to the Yukon, our continent has been well-combed by prospectors, ancient and modern, until most of those bonanzas have been located and worked that had their signs sticking out of the ground, as if saying to all who passed that way, 'Here I am, come and get me.' In future, then, the proverbial tenderfoot luck and prospector's grind must give way, in large measure, to logical reasoning and deduction, well exemplified by Parke Channing's brilliant work at Miami.

"In exploratory work, especially, whether of examination prior to purchase or undertaken in the development of ore reserves, the part played by microscopic analysis of rock sections is most important. Yet there are instances in which geological theories must fail in advance of exploratory work and the discovery of 'the law of the camp.' Such instances are those in which detached ore bodies or shoots lie in different planes or horizons, as they do in Nickel Plate mountain, Hedley, British Columbia. Here, the tilted and contorted sedimentaries are penetrated and parted along their bedding planes by spurs and sheets of monzonite that have so altered and silicified the limestones at points of contact as entirely to mask their identity to the naked eye and to cause experienced geologists to classify them as quartzites, by which name they were known for years, before rock sections were made, just as the monzonites were called andesites. Microscopic analysis showed the presence of the critical minerals and indicated deep-seated action, resulting in the formation of true contact metamorphic deposits of arsenical pyrites containing gold and presenting peculiar and unique mining and geological problems as well as a delicate problem in professional ethics and commercial expediency.

"Prior to 1909, when it changed hands, there was but one known ore-bearing horizon on this property, nor was any other discovered until two years later. When, therefore, this known horizon, or contact, showed signs of exhaustion and when systematic surface prospecting and extensive underground exploration had failed to open new ore bodies, a comprehensive plan for development became necessary, and, owing to the absence of guiding indications such as veins, fissures, mineralizing dikes, etc., the preliminary estimates of the possible cost of this work ran very high. Pay-ore might occur anywhere in depth, or nowhere at all. So far as could be foreseen, it meant a detailed exploration of the entire mountain and the odds against finding pay-ore with a minimum of work and expense appeared very great. Moreover, competent geologists had already been consulted and there seemed to be no hope of aid either from analagous reasoning or geological deduction, inasmuch as this formation is unique, according to the best authorities.

"Consequently, without a reasonably positive assurance of success, which could not, of course, be given, the owners were reluctant to authorize the expenditure, especially since it had become necessary to remodel the entire plant owing to the disappearance of free gold with depth. They determined, therefore, to sell, at a profit on their investment, to others who stood ready to purchase on the showing at that time, and to take the very long 'mining chance' that remained. The new owners entered at once upon the necessary expenditures for plant improvement and development, and, after some two years' work, when the old workings were practically exhausted, were very fortunate in finding another ore-bearing horizon or contact, several hundred feet below the lowest of the old workings, thereby prolonging the life of the property and once more proving the fact that long odds sometimes win out.

"Now the ethical question, and the commercial expendiency, involved in this case was this: In cases of grave doubt, should managers advise and encourage heavy expenditures solely on the basis of the 'mining chance,' thereby risking a total loss, or should they advise for safety and an assumed profit? At first sight there would seem to be but one answer to such a question, assuming, of course, that the first duty of a manager to his principals is to protect them from ultimate loss. Yet, as everyone knows, mine owners in general more readily forgive advice that causes heavy loss when ore does not materialize than they do advice that loses them the profit others may make out of ground they once owned, notwithstanding the fact that the percentage of cases under the first condition is vastly in excess of that under the second, as the history of mining conclusively shows.

"It is precisely this peculiarity of human nature that decides many examining engineers, mine managers, and geologists in taking long chances on unduly favourable predictions. It is true that conditions are gradually changing in this respect as regards the heavier mining investors. These men are learning to appreciate conscientious reports and conversative advice, and they value accordingly the services of those who make them or give it. But with the general investing public it is still as it always has been—optimism is expected and demanded and the only unpardonable sin is advice that loses a possible profit that others realize, no matter how long the odds.

"To return then to Professor Stewart's excellent paper—the aids offered by rock sections in exploratory work cited by him would doubtless fail in formations similar to the one just described—at least in advance of exploratory work sufficient to demonstrate the 'law of the camp' if this were possible, which at present writing and in this instance appears doubtful."

# NAMES OF MINERALS

By Wm. Thomlinson, New Denver, B.C.

The following was written for publication in a mining district of British Columbia. It was prove readable as well to some of those interested in minerals and resident in some of the many other mining camps in which The Canadian Mining Journal is read:

Many prospectors and miners have a habit of making rude remarks regarding the technical names of rocks and minerals. They may be justified in doing so, or, perhaps, it may be, that as the Arabs say, "they don't know what they don't know," therefore may be excused.

As a sort of pastime I have looked up this matter of technical names and find that really there is as much "method in the madness" of the mineralogists as in the work of other men who are responsible for the names used in botany, horticulture, pomology, and so on.

Our worthy metal-miners rail at such names as Rhodonite, for a rose-pink mineral, but are respectfully silent when a botanist calls a shrub a Rhododendron; Cauliflower, for a vegetable, and Duchess of Oldensburgh, for an apple, are quietly accepted; but when a miner, who has been some to school, speaks of calcite, bornite, argentite and so on, some proudly practical friend is sure to retaliate with professional words used mostly by sailors, teamsters, and troopers.

More in sorrow than in anger I shall try to show that the technical names for minerals, such as Fluorite, Bornite, Smithsonite, etc., are nearly as appropriate as "Blue John," "Black Jack," "Dry-bone ore," "Horseflesh ore," "Turkey-fat ore," "Spiderleg," and "Mustard" gold.

Upwards of eight hundred different minerals are known to mineralogists and it was evidently "quite a job" to find for them all names not previously taken for use in other branches of science. However, they seemingly did the best they could under the circumstances.

Referring to about two hundred of the commoner economic minerals, the names are mainly formed from the names of places where the minerals were first found; from names of persons who first noted the minerals or proved their composition, or some peculiarity of shape, colour, weight, or other physical property of the mineral.

The following are examples of how the names are derived:

### From Names of Places.

Altaite, telluride of lead, found in the Altai mountains, Russia.

Bauxite, hydrous-oxide of aluminium, at Baux, in France.

Franklinite, an iron-zinc-manganese mineral, at Franklin, New Jersey, U.S.A.

Calaverite, telluride of gold and silver, found in Calaveras county, California.

Muscovite, white mica, first used for windows at Moscow, Russia.

### From Names of Persons.

Sperrylite, arsenide of platinum, after Mr. Sperry, who discovered the mineral at Sudbury, Ontario.

Stephanite silver, antimony and sulphur, "brittle silver ore," after a Grand Duke Stephan of Austria.

Proustite, silver, arsenic and sulphur, "arsenical ruby silver ore," after Dr. Proust, who first noted the difference between this mineral and the antimonial ruby silver ore, Pyrargyrite.

Bornite, copper, iron and sulphur, "peacock copper ore," after Mr. Born, who first determined its composition.

Millerite, Garnerite, Smithsonite, and a large number of others are named in this manner.

### From Forms of Crystals.

Tetrahedrite, "gray copper ore," from two Greek words meaning for faces or sides, the mineral, when crystalized, having a four-sided wedge-like form.

Octahedrite, titanium oxide, similarly because of its eight-sided form.

Orthoclase, potash feldspar, from two words meaning right and cleavage, the mineral splitting or having cleavage lines at right angles.

### From Colour and Other Peculiarities.

Hematite, an oxide of iron, from a Greek word meaning blood, the mineral when powdered has a dark red blood colour.

Rhodontie, manganese silicate, from a Greek word for rose, the mineral has a rose-pink colour.

Azurite, a carbonate of copper, of azure blue colour.

Maganetite, a black oxide of iron, so named because it is highly magnetic.

Barite, sulphate of barium, "heavy spar." Name from a Greek word meaning heavy.

Tungsten, from Swedish words meaning heavy stone, its great weight being noticeable.

Petroleum, derived from the Latin words meaning literally rock oil. Many minerals and economic substances are named in this manner.

Some minerals are named after the principal metal or element found in their composition, as cobaltite, nicolite, bisceuthite, and so on. A number of metals and minerals were known and used ages ago, and in many cases the old Greek, Latin, and other names are still used by chemists and other scientific men. These are examples: Gold, aurum; silver, argentum; copper, cuprum, also chalco, lead, plumbum; iron, ferrum, also sideros; antimony, stibium; tin, stannum; lime, calx. From these are derived such names as argentite, sulphide of silver; cuprite, red oxide of copper; chalcocite and chalcopyrite, two other copper-bearing minerals; siderite, carbonate of iron; stibnite, sulphide of antimony; stannite, sulphide of tin and copper; calcite, "lime spar," carbonate of lime.

It is not assumed that scientific men are entirely blameless in the matter of coining or selecting names for rocks, minerals, etc., but it may be reasonable to remember and consider the size and difficulty of the task of finding such a large number of suitable names.

However, if any fiercely practical prospector or miner will be good enough to furnish a list of, say, 600 short, apt, and easily pronounced names, suitable for rocks and minerals, the writer will be happy to re-forward the same for careful consideration to the next congress of "rock sharps," "mining experts" and mineralogists.

# THE COPPERMINE COUNTRY

By J. B. Tyrrell

(Continued from our last issue.)

After Hearne's visit in 1771 no white man visited the country for fifty years, until Sir John Franklin arrived at the head waters of the river, and then descended and made a survey of it from Point Lake to the Arctic Ocean. Franklin's account of the country is interesting. He states:

"We rejoined our hunters at the foot of the copper mountains, and found they had killed three musk-oxen. This circumstance determined us on camping to dry the meat, as there was wood at the spot. We availed ourselves of this delay to visit the copper mountains in search of specimens of the ore, agreeably to my instructions; and a party of twenty-one persons, consisting of the officers, some of the voyagers ,and all the Indians, set off on that excursion. We travelled for nine hours over a considerable space of ground, but found only a few small pieces of native copper. The range we ascended was on the west side of the river, extending W.N.W. and E.S.E. The mountains varied in height from twelve to fifteen hundred feet. The uniformity of the mountains is interrupted by narrow valleys, traversed by small streams. The best specimens of metal we procured were among the stones in these valleys, and it was in such situations that our guides desired us to search most carefully. It would appear that when the Indians see any sparry substance projecting above the surface, they dig there; but they have no other rule to direct them, and have never found the metal in its original repository. Our guides reported that they found copper in large pieces in every part of this range, for two days' walk to the northwest, and that the Esquimaux come hither to search for it. The annual visits which the Copper Indians were accustomed to make to these mountains, when most of their weapons and utensils were made of copper, have been discontinued since they have been enabled to obtain a supply of ice-chissels and other instruments of iron by the establishment of trading posts near their hunting grounds. That none of those who accompanied us had visited them for many years was evident, from their ignorance of the spots most abundant in metal.

"The impracticability of navigating the river upwards from the sea, and the want of wood for forming an establishment, would prove insuperable objections to rendering the collection of copper at this part worthy of mercantile speculation."

Among the members of Franklin's party was Sir John Richardson, the great naturalist, and his account of it is much more detailed than that given by his chief and is here appended:

"The Copper Mountains appear to form a range running S.E. and N.W. The great mass of rock in the mountains seems to consist of felspar in various conditions; sometimes in the form of felspar rock or claystone, sometimes coloured by hornblende, and approaching to greenstone, but most generally in the form of dark reddish-brown amygdaloid. The amygdaloidal masses, contained in the amygdaloid, are either entirely pistacite (epidote), or pistacite enclosing calc-spar. Scales of native copper are very generally disseminated through this rock, through a species of trap tuff which nearly resembled it, and also through a reddish sandstone on which it appears to rest. When the felspar assumed the appearance of a slaty claystone, which it did towards the base of the mountains on the banks of the river, we observed no copper in it. The rough and in general rounded and more elevated parts of the mountain are composed of the amygdaloid; but between the eminences there occur many narrow and deep valleys, which are bounded by perpendicular mural precipices of greenstone. It is in these valleys, was crystallized in rhomboidal dodecahedrons. We also found some large tabular fragments, evidently portions of a vein consisting of prehnite, associated with calcareous spar, and native copper. The Indians dig wherever they observe the prehnite lying on the soil, experience having taught them that the largest pieces of copper are found associated with it. We did not observe the vein in its original repository, nor does it appear that the Indians have found it, but judging

**On Point Lake, June 25th, 1821**

amongst the loose soil, that the Indians search for copper. Amongst the specimens we picked up in these valleys, were plate of native copper; masses of pistacite containing native copper; of trap rock with associated native copper, green malachite, copper glance or variegated copper ore and iron-shot copper green; and of greenish grey prehnite in trap (the trap is felspar, deeply coloured with hornblende), with disseminated native copper; the copper, in some specimens. from the specimens just mentioned, it most probably traverses felspathose trap. We also picked up some fragments of a greenish-grey coloured rock, apparently sandstone, with disseminated variegated copper ore and copper glance; likewise rhomboidal fragments of white calcareous spar, and some rock crystals. The Indians report that they have found copper in every part of this range, which they have examined for thirty or forty miles to the N.W., and that the Esquimaux

come hither to search for that metal. We afterwards found some ice-chisels in possession of the latter people twelve or fourteen inches long, and half an inch in diameter, formed of pure copper."

In the same year, 1821, Franklin and Richardson found trap rocks of the copper-bearing series eastward along the Arctic coast for nearly two hundred miles, or as far as the east side of Bathurst Inlet, though no copper or copper ore seems to have been found in them.

On Franklin's second journey in 1826 Richardson recognized the existence of rocks of similar character at a number of points along the Arctic coast for 200 miles west of the Coppermine river.

From the description quoted above it would appear that the rocks on the Coppermine river are similar to the copper-bearing rocks on Lake Superior, and that the conditions under which the copper occurs are also similar to them under which it occurs on Keewenaw Poin on the south shore of Lake Superior. Speaking broadly, these rocks would appear to indicate a repetition to the north of the great Archean protaxis of the conditions which have prevailed on Lake Superior to the south of it.

tained in a letter from Mr. V. Stefansson, dated Langton Bay, July 1st, 1911, and addressed to Dr. H. C. Bumpus, Director, American Museum of Natural History, New York City. Mr. Stefansson writes as follows:—

"That copper was to be found on the Coppermine river has been generally known for more than a century; we found, however, that even the Eskimos nearest the river, while they pick up some copper on the banks occasionally, depend chiefly on the richer deposits north of Dismal lake. Neither of these regions is rich in native copper, however, compared with the mountains northeast of Prince Albert Sound" (on Victoria Land).

This is the first record of the occurrence of native copper or the copper-bearing rocks on any of the large islands in the Arctic Ocean, and as Prince Albert Sound is probable accessible to ocean-going ships by way of Behring Sea, the locality might be much easier to explore and mines might be much more readily developed than in the districts on the mainland in the vicinity of the Coppermine river.

Judging from the evidence here presented, the existence of a great copper-bearing area on the Arctic coast

**Mouth of Coppper Mine River, July 20th, 1821**

Since Franklin and Richardson visited, mapped, and described this region, very little attention has been paid to it, though Thomas Simpson and John Rae both crossed the Coppermine river, and make mention of it in their journals. .

The traps and associated rocks may cover a very much larger area than we know of at present, for, in 1903 I found them on the north shore of Doobaunt lake, and on the Doobaunt river below the lake. As late of 1902 the late David Hanbury ascended Coppermine river as far as the portage to Great Bear lake in his journey from Hudson Bay to the Mackenzie river, and he has mentioned in his book that one of his men named Sandy, while tracking up the river, "was nearly tripped up by a chunk of native copper on the shore. I weigher about twelve pounds."

An important addition to our knowledge of the copper-bearing rocks of the northern coast of America has just been brought to my attention by Dr. James Douglas, of New York, and I am permitted to publish it through the kindness of the secretary of the American Museum of Natural History. The information is con-

of America near the Coppermine river is certain, and it is also reasonably certain that that area is very much more extensive than the copper-bearing area south of Lake Superior, extending, as it does, from Victoria Land and the hills west of the Coppermine river, to the shores of Bathurst Inlet far to the east, but whether native copper will be found anywhere as plentifully distributed or in such rich segregations as on Keewenaw Point, is yet quite uncertain. As the copper-bearing area in Northern Canada is larger it is quite possible that the mineral deposits may be similarly larger, and it is worth while for the Canadian people to find out whether they have in this far northern country a great reserve of copper ore for the use of themselves and the world when the mines that are now being worked shall become depleted. It may seem foolish for us to spend money at the present time to determine the existence of bodies of ore which we cannot use, but copper is one of the most useful metals in the world to-day, and it behooves a nation like an individual to study its ore reserves in order that it may deal with them wisely, and have them developed in such a way

HENDERSON TALC MINE, MADOC, ONT.
Pillar and Wall Solid Talc.—This is second of series of underground photographs of Canadian Mines.

that they will bring the greatest benefit to the people. Therefore, I say that we Canadians, knowing that we possess an area of potential wealth in copper in that far northern country, should examine it carefully and find out whether we have a natural asset there that, if intelligently used, will add greatly to the wealth of the nation, or whether we are prepared to hand over that possible asset without knowing whether it is valuable or not, to private individuals, who, by the expenditure of a little capital and energy, may make enormous fortunes as a result of our negligence.

# NEW TYPE MINE LOCOMOTIVE

The accompanying illustrations show a new type of mine locomotive which has recently been placed on the market by the Baldwin Locomotive Works and the Westinghouse Electric & Mfg. Co. The notable features are the open, cast-steel bar frame and the specially designed commutating pole mine motors shown in Figs. 2 and 3.

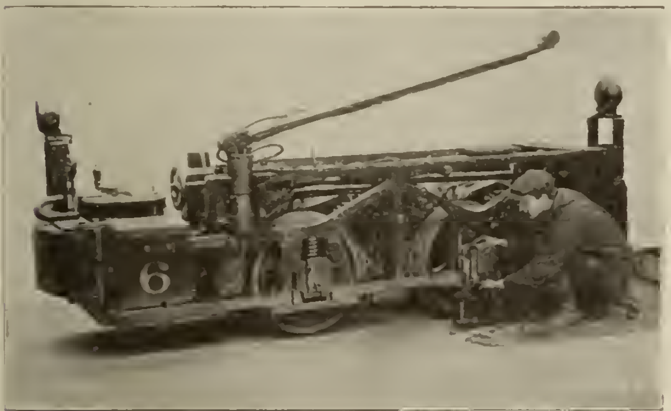

Fig. 1

This type of locomotive is distinguished for its accessibility, simplicity, durability and strength. It is claimed that it will operate satisfactorily under the worst conditions with minimum attention and maintenance expense. The frame is designed to give maximum strength and to allow ready access to all parts so that the locomotive can be inspected and overhauled, when

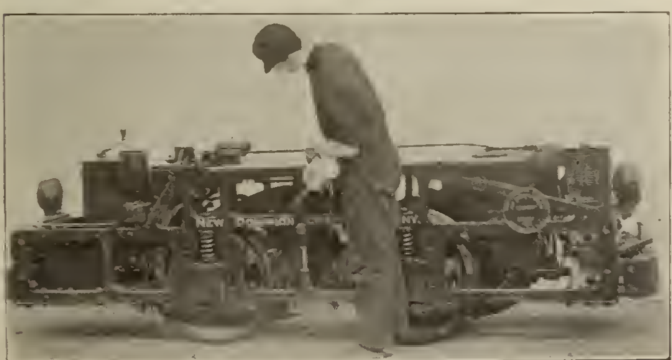

Fig. 2

necessary, in the least possible time. The construction is the same as that used on heavy Baldwin steam freight engines.

The open frame gives much better ventilation to the motors and resistance than that obtained by armour-plate frame construction. The motors, brake rigging, brake shoes and sand boxes are easily accessible. The upper parts of the motors and armature bearing housings can be removed without disturbing the suspension, so that each part of the motor is exposed for inspection. To remove the grid resistors the only work necessary is to take off the locomotive covers and loosen the bolts and terminals that hold the resistor frames in place.

An attractive feature introduced on locomotive with outside frames is the Vauclain removable gib. To remove a journal box with this gib, it is only necessary to

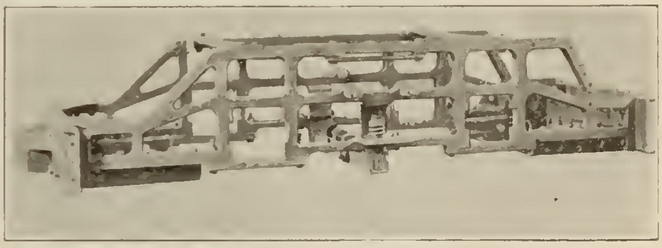

Fig. 3

drop the binder and take the weight off the journal box. The journal box may then be slipped out from the side as shown in Fig. 4. On locomotives with inside frames the journal box cellars are arranged to be easily dropped out for re-packing. If it is desired to take out a set of wheels and axle, this may be done without disturbing the motor suspension or connections by simply

Fig. 4

blocking the motors in place and removing the binders. The wheels may then be dropped.

The motors used in this locomotive have decided advantages over other types, of which their excellent commutation, due to the use of commutating poles, is of first importance, because it increases reliability of operation and cuts down the cost of maintenance. With good commutation, the commutator and brushes require very little attention and brush renewals are seldom necessary. The insultation of armature and field coils remains in good condition for a much longer time than on other types because of the absence of copper and carbon dust.

The frames of the motors are made of cast steel and are split diagonally. The axle bearings and suspension nose are on the lower half of the frame, so that the upper half, the armature, and bearing housings can be removed without disturbing the suspension or axle brackets. The armature core is mounted on a spider to which it is keyed, making it possible to remove the shaft without disturbing the windings, and also reinforcing the shaft against bending. Large openings are provided in the spider and through the core to give sufficient ventilation.

## NATIONALIZATION OF MINES

The following clipping goes to prove that Mr. Keir Hardie, M.P., can be as visionary as the best:

"London, Feb. 18.—The Miners' Federation of Great Britain has declared by a majority of 60,000 in a total vote of 232,000 in favour of a five-day working week for miners. The executive committee, however, has adopted a resolution saying that the majority is not large enough for any action to be taken and that there must, therefore be another vote.

"J. Keir Hardie, M.P., has stated that within a few months the labor party, in conjunction with the miners' federation will begin a great campaign for the nationalization of the mines. He says that a bill to accomplish this is now being drawn and will soon be presented in Parliament. According to the terms of the bill, the mines are to be paid for with government stock, a second fund being provided to redeem the stock within a given period.

"The mines would not be bought on stock exchange quotations. That would mean that they would cost at least $750,000,000, but another way of setting a price would be adopted by which the cost to the government would be reduced to not more than $375,000,000.

"If the mines were nationalized, Mr. Hardie declares, coal would be sold at a fixed price, just as postage stamps are at present, and the cost of coal to the consumer would probably not exceed one-half of what was now being paid. By the plan under consideration, the mines would not be controlled by a manager appointed by the government, but would be managed on much the same lines as the national railways in France. Every time there was a dispute a committee of workmen appointed by the workmen from their own ranks should meet to consider the dispute and the decision of that committee should be binding upon the manager as well as the workmen."

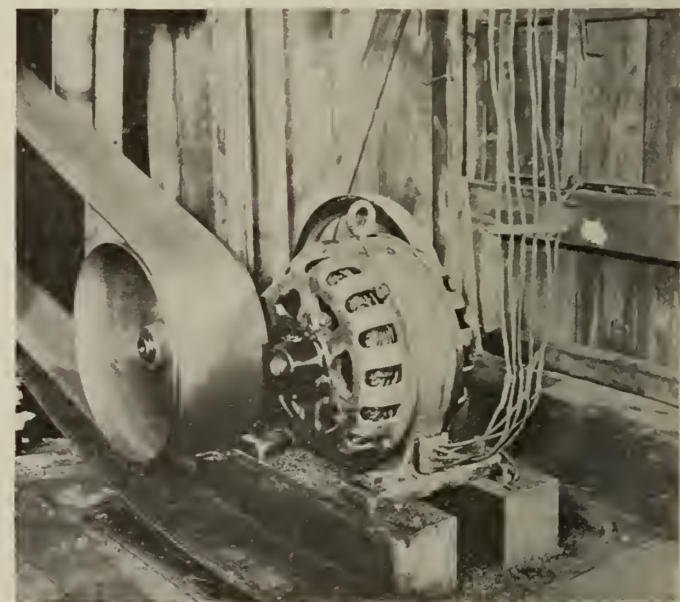
## TWO-SPEED A.C. MOTOR FOR MINE FAN DRIVE

An excellent emaple of the efficient adaptation of electricity to mine service is illustrated in the accompanying picture, which shows a two-speed, alternating current, three-phase, 60-cycle, 440-volt motor, belted to a Guibal 12-foot fan installed in the Greensburg No. 1 mine of the Keystone Coal Company, near Greensburg, Westmoreland county, Pa.

The force of miners is considerably less at night than during the daytime, and consequently it is desired to run this fan at only about one-half the speed at night that is required during the day. For this service there was selected a Westinghouse type 661 squirrel-cage type induction motor, with a rating of 7½ horse-power at 600 r.p.m., and 15 horsepower at 1,200 r.p.m.; the other characteristics being as mentioned above.

The change in speed is accomplished by changing the number of poles. The stator of the motor is provided with two windings; one of which gives 6 poles, resulting in a speed of 1,200 r.p.m., and the other gives 12 poles, with a speed of 600 r.p.m. The connections are changed for one set of winding to the other by the controller. This is a most efficient form of control for an installation of this kind, as the motor of control for an installation of this kind, as the motor can be operated at low speeds at its highest efficiency, there being no losses in the control resistance. The motor itself is particularly well adapted to this class of service on account of its rugged characteristics, which insure great reliability of service.

Current for the operation of this motor is furnished by the West Pennsylvania Electric Company. In order to determine the results obtained from the installation, tests were made by Mr. C. V. Elliott, electrical engineer of the Lighting Company, which showed the following results:



The fan is 5 feet 6 inches wide, and the depth of blades 3 feet 6 inches. When running at 120 r. p. m., with 1.5 inches water gauge, or an equivalent pressure of .87 ounces per square inch, 46,200 cubic feet of air per minute were delivered. The motor in performing this work took 9.6 k.w., giving an efficiency of 63.03 per cent. for the outfit. When running at half speed, or 60 r.p.m., with .6 inch water gauge, or .29 ounce pressure per square inch, 14,850 cubic feet per minu e were delivered, and an efficiency of 58.33 per cent. was obtained.

These results are particularly important, as they show economy in the use of purchased power, which is becoming standard practice where alternating current is available.

# NEW COAL FIELDS IN ENGLAND

The following extract from the Boston News Bureau has considerable interest:

Boston.—The Boston News Bureau some months ago gave brief notes of the discovery of coal by borings in the county of Kent, England, where for a thousand years it has been believed impossible that coal could be found.

Now the London people are in a wordy warfare as to the value of Kent coal. It is indeed difficult to eradicate the British prejudice or to convince a dweller in London that there is just as good coal to the southeast as to the north and west of London, and coal in tens of thousands of acres.

When Sir Edward Watkin, in 1891, started his Channel tunnel at the Shakespeare cliff just below Dover, coal was not in his calculation, if, indeed, in his imagination; but when the British government put an embargo upon the Channel tunnel enterprise, holding that England was an island and must so remain, Sir Sdward Watkin turned his men and machinery to boring for coal, as there were indications that the coal field on the French side of the channel might extend into England. He found the first seam of coal at a vertical depth of 1,600 feet in 1892, or 20 years ago.

This was the nucleus of "Kent Collieries, Ltd.," which has met with indifferent success, but has spent more than a million dollars in wrestling with engineering and water problems at depth, but is now, it is believed, nearing the base of commercial production. In 1904, however, systematic boring of the country north and east of the railroad line from Canterbury to Dover was begun under the auspices of Kent Coal Concession, Ltd., and in 1906 the first payable seam was found at the Walde shaft boring six miles northwest of Dover. Now the whole country has been thoroughly explored and 13 bore holes have proven at a depth of between 1,000 and 3,500 feet coal seams aggregating about 30 feet vertical thickness throughout and extending over an area of about 100 square miles. It is said that this coal can be transported to London two shillings cheaper per ton than any other coal by reason of its proximity to the metropolis, and the quality of coal is declared as good as the South Wales steam coal and better than any other variety in England.

It is estimated that there are 10,000 million tons of coal within this area. The Snowdown and Tilmanstone collieries have at last after a great deal of trouble penetrated into the coal measures. Railways are being constructed and shipments should be into London next year.

Not less significant than the Kent discoveries is the development of the eastern extension of the Midlands coal field in the southeast of Yorkshire and the counties of Nottinghamshire and Lincolnshire. What are without doubt the finest collieries in Great Britain are to-day in the district immediately adjoining Doncaster, in a countryside that for centuries has been purely pastoral. The sum of £250,000 is said to be a usual outlay on the capital expenditure of a colliery in that district. The population has increased beyond the housing capacity, and this once peaceful countryside has experienced the growing pains of a "boom" resembling more the growth of a Canadian prairie town than anything else.

The discovery of the Kent coal seams was the indirect result of a thwarted endeavour in another direction, but the discovery of the extension of the Midlands coalfield was the result of a process of careful industive geological reasoning, chiefly to be credited to Professor Lapworth, who from indications noticed by him near Selby, Yorkshire, came to believe that the Permian formation of East Yorkshire and North Lincolnshire was laid unconformably on an anticline of the Carboniferous rocks. Actual researches proved that his belief was correct, and instead of the valuable seams of the Midlands coalfield being buried under inaccessible depths of Permian formation they were found to exist at depths quite possible for modern methods of coal extraction.

The importance of these two new coal fields to England and the Empire at large can hardly be overestimated, and it is possible that even Englishmen themselves have scarcely taken in the full significance of the new coal fields to the future of their country.

---

The Standard Underground Cable Co., of Canada, Limited, has established new branch offices at Montreal, Quebec, and Winnipeg, Manitoba, in order to facilitate the prompt handling of their growing business. The Montreal office will handle all business from the province of Qubec and the eastern part of the province of Ontario. The Winnipeg office will handle all business coming from the provinces of Alberta, Saskatchewan, Manitoba and a portion of the province of Ontario lying west of Fort William. The general offices of the company at Hamilton, Ont., will handle all business from the central and northern portions of the province of Ontario. Business originating in the province of British Columbia, Alaska, and Yukon territories will be handled by the Seattle, Wash., office of the company, and business from the Maritime Provinces will be handled by the Boston, Mass. office. This is a temporary arrangement in order to secure prompt service immediately for customers in those districts until the volume of business justifies the establishing of separate offices in the Dominion.

---

# ALLOYS OF COBALT WITH CHROMIUM.

A recent paper contributed to the Transaction of the American Institute of Mining Engineers, by Mr. Elwood Haynes, describes the methods employed in and the results obtained from alloying cobalt with chromium. By the addition of tungsten the hardness of alloy increases. Thus with 10 per cent. tungsten, the metal while still forging readily, is suitable for making both cold chisels and wood working tools. With 20 per cent. tungsten the alloy is decidedly harder, and will make good lathe tools for cutting steel and other metals at moderate speed. With from 25 to 40 per cent. tungsten a very hard alloy results, the tools made from which are very strong and retain their hardness at speeds which almost instantly destroy the cutting edge of a steel tool. When the tungsten reaches 40 per cent. or more, the alloy becomes so hard that it will not only scratch glass, but will readily scratch quartz crystal. Again when molybdenum is added to a 15 per cent. cobalt-chromium alloy, the latter hardens rapidly as the molybdenum content is increased. With 40 per cent. mlybdenuin the alloy becomes exceedingly hard and brittle, cuts keenly and deeply into glass, and scratches quartz crystal with ease. Generally the color and lustre of these alloys, after polishing, are brilliant, and it is stated that they seem to resist atmospheric influences equally well as the binary alloy of cobalt and chromium.

# PERSONAL AND GENERAL

Mr. Frank M. Perry has left for Cobalt to supervise development work in several Gillies Limit claims. Mr. Perry will return in time to attend the annual meeting of the Institute at Ottawa.

Mr. J. S. Fraser, of Nova Scotia, who has been superintendent of the Neville Island and Allegheny plants of the Carnegie Steel Company, has been transferred to the Clairton Steel Works, where he will be in charge of the blast furnaces.

Mr. G. S. Scott is in England on mining business. His address until early March is Copse Close, Coombe Lane, Wimbledon, London, S.W.

Dr. Alfred E. Barlow, of Montreal, attended the annual meeting of the American Institute of Mining Engineers, in New York, on February 18, 19 and 20, as the guest of the New York section.

The secretary of the Canadian Mining Institute has been informed that Mr. W. Fleet Robertson, Provincial Mineralogist of British Columbia, intends to be present at the annual meeting of the Institute in Ottawa next week. Mr. M. E. Purcell, superintendent of the Consolidated M. & S. Company's Rossland mines, and chairman of the Western Branch of the Institute will also attend upon the invitation of the Council.

Mr. John Hopp, of Barkerville, B.C., is at present in Montreal, and will remain in the East until the end of the first week of March.

Mr. J. Oblaski has been re-elected President of the Chambre de Commerce Francaise of Montreal.

The three year contract of Mr. A. B. W. Hodges as general manager of the Cerro de Pasco Mining Company, terminated on February 28th of this year. Mr. Hodges leaves at once for Canada and the United States. He will visit British Columbia during July or August.

Mr. J. O'Brien has brought suit in Montreal against the Union Abitibi Mining Company. The plaintiff's claim is based upon injury done to certain timber limits in the Pontiac district, Quebec. The defence claims that as the timber was used for local purposes and not marketed, there was nothing illegal in cutting it.

Mr. M. K. Rodgers, of Seattle, Washington, well known in British Columbia in connection with the development to important mines of the Nickel Plate group, in Similikameen district, and the Hidden Creek group, near Observatory inlet, is in Mexico. The former mines, now owned by the Hedley Gold Mining Co., paid in 1912 dividends totalling 30 per cent. on the company's issued capital of $1200,000 (amount of dividends $360,000) as compared with 25 per cent. in 1911. The Granby Co. owns the Hidden Creek group, and rerecently its directors authorized the expenditure of about $2,000,000 in further underground development, and provision of smelting, hydro-electric power, transportation, and shipping dock facilities, together with buildings for mechanical purposes and accommodation of the company's officials and workmen.

Mr. W. L. Bell, superintendent of the British Columbia Copper Co.'s smelting works at Greenwood, Boundary district, B.C., recently spent a few days in Spokane, Washington.

Mr. Henry Clark has been requested to address the Western Branch of the Canadian Mining Institute on the subject of "Modern Surface Equipment of Coal Mines," and in connection therewith to show lantern-slides and models he has, to illustrate this subject. It is planned to have the benefit of Mr. Clark's address at a meeting of the branch to be held in Nanaimo, Vancouver island, early in March.

Mr. E. E. Campbell (B.Sc. McGill, 1908), of the Granby Consolidated Mining, Smelting and Power Co.'s engineering staff, was a passenger on the steamer "Cheslakee" when that vessel filled with water and sank at the wharf, Van Anda, Texada island, B.C., but fortunately he was one of those who got ashore without injury. When the steamer took such a strong list that water began to pour into her, she was headed for the dock, which she reached in time for most of those on her to get ashore, but several others were drowned.

The Mines Branch of the Canada Department of Mines has published as an advance chapter of the "Annual Report on the Mineral Production of Canada During the Calendar Year 1911," a pamphlet on "The Production of Copper, Gold, Lead, Nickel, Silver, Zinc, and Other Metals" in that year, prepared by Mr. Cosmo T. Cartwright, Assistant Mining Engineer, Division of Mineral Resources and Statistics.

Mr. Wm. B. Bornberg, of Spokane, Washington, manager for the Treasure Mountain SilverLead Co., which, during the past year has been opening a new mining property, situated about 20 miles about Otter flat, Tulameen district of British Columbia, has been in Victoria, interviewing the Provincial Government with the object of getting a wagon road constructed so as to make the new camp more accessible than it is with only a trail to it for about 18 miles beyond the end of the nearest wagon road.

Mr. W. J. Elmendorf, of Victoria, B.C., general manager for the Portland Canal Tunnels, Limited, is supervising the work of driving a 2,000-ft. cross-cut adit undertaken by the company on his recommendation, with the object of proving whether the veins of ore opened at comparatively shallow depths on several claims, continue down to the depth to be explored by this low-level tunnel.

Before leaving the British Columbia Copper Co.'s Mother Lode mine, near Greenwood, B.C., for Sudbury, Mr. E. Hibbert was presented with a gold watch and chain, valued at $210, by the employees who had worked under him at that mine. Mr. F. S. Norcross, who had been superintendent at the Rawhide mine, Phoenix camp, also in Boundary district, has been appointed to succeed Mr. Hibbert as superintendent of mines, and Mr. James J. Johns, for years foreman at the Mother Lode, has been promoted to the position of superintendent of that mine.

Mr. A. B. W. Hodges, of Lima, Peru, general manager for the Cerro de Pasco Mining Co., is stated by the Grand Forks Gazette to be expected to shortly visit Spokane and Grand Forks. Mr. Hodges was for some years manager in British Columbia for the Granby Consolidated M. S. and P. Co. and made Grand Forks his headquarters.

Mr. John Hopp, who is the largest hydraulic placer-gold mining operator in Cariboo mining division, British Columbia, recently left that province on a visit to

Philadelphia and New York. It is probable he will also visit the larger cities of Eastern Canada before returning to the West.

Mr. Andrew G. Larson, of Vancouver, B.C., has been spending a winter vacation in Los Angeles, Southern California. From that city he sent a "good-luck" telegram to the Old-Timers' Association while that organization was holding a reunion in Rossland recently.

Mr. E. G. Montgomery (B.Sc., McGill, 1908), is assistant superintendent at the Consolidated Mining and Smelting Company of Canada's Star-War Eagle group of gold-copper mines in Rossland camp, British Columbia.

Mr. J. L. Parker has been spending the winter on his Lee Lake ranch, near Burmis, southwest Alberta.

Mr. M. E. Purcell, of Rossland, B.C., superintendent of the Consolidated Mining and Smelting Company of Canada's Centre Star-War Eagle group of mines, and who is chairman, for the current year, of the Western Branch of the Canadian Mining Institute, will be the guest of the Institute at the forthcoming annual general meeting, to be held in Ottawa. Mr. Purcell is an active member of the branch, with which he has been associated from the time of its inception five years ago.

Prof. Milnor Roberts, of Seattle, Washington, U.S.A., dean of the College of Mining of the University of Washington, is endeavouring to arrange for his senior mining engineering class to spend part of the spring vacation in Boundary district, British Columbia, where the big copper mines and smelteries would afford them much instructive information. It is planned to also visit Republic gold camp and Chewelah copper camp, both situated in the interior of the State of Washington.

Mr. Wm. Fleet Robertson, provincial mineralogist for British Columbia, has arranged to attend the meeting of the International Geological Congress organization committee, to be held in Ottawa on March 4, and afterward the annual general meeting of the Canadian Mining Institute. Mr. Robertson is a McGill graduate (B.A.Sc., 1880), a past councillor of the Institute, and an ex-chairman of the Western Branch of the Institute.

Mr. Robert C. Sticht, now general manager of the Mt. Lyell Mining and Railway Co., who recently removed his headquarters from Queenstown, Tasmania, to Melbourne, Australia, was formerly well known in North America as a metallurgist.

Mr. G. Stilwell, superintendent for the Silverton Miles, Ltd., of the Hewitt-Lorna Doone group of mines, British Columbia, has spent a number of years opening that mining property, on which a large amount of underground development has been done under his direction. The ore contains silver, lead, and zinc; some of the finest specimens of ruby silver seen in Slocan district have been found in these mines, which will soon have the added distinction of being the first in Kootenay district, in connection with which the Minerals Separation flotation process is in use. Mr. M. S. Davys, managing director of Silverton Mines, Ltd., who resides at New Denver, Slocan lake, is keeping in close touch with the erection and equipment of a new concentrating mill for the company, which is being put in under the direct supervision of Mr. C. Hanckel, formerly with the Zinc Corporation, Limited, at Broken Hill, New South Wales.

Mr. Thos. R. Stockett, of Nanaimo, Vancouver island, B.C., general manager for the Western Fuel Company, with operating coal mines at or near Nanaimo, known, respectively, as No. 1 Shaft, Protection Island, and Brechin mines, continues to take much interest in provision for the protection of the miners. His company was the first in British Columbia to obtain for its own use oxygen-breathing apparatus, and, too, the first to erect and equip a mine-rescue training station. In these matters Mr. Stockett has all along had the active co-operation of his superintendents, first of Mr. Thos. Graham, now chief inspector of mines for British Columbia, and then of Mr. Thos. McGuckie, the present general superintendent. There are now in the company's employ 65 men who have taken the full mine-rescue training course and obtained certificates of competency in that work. An evening session of the meeting of the Western Branch of the Canadian Mining Institute, to be held in Nanaimo shortly, is to be occupied, first, in hearing addresses on mine-rescue matters, and afterward in holding a "smoker" which will be largely attended by the company's mine-rescue "graduates" and their fellow miners.

Mr. Wm. Thomlinson, of New Denver, B.C., who some time since contributed a paper on "Notes on Minerals Found in Slocan District, B.C." (as Canadian Mining Journal for November 15, 1911, p. 737) recently prepared an interesting article on "Names of Minerals."

The University of Washington, Seattle; State College of Washington, Pullman; and University of Idaho, Moscow, Idaho, have been giving short mining courses which have been well attended by miners, some of them for the second year.

Mr. George E. Wearing, formerly engaged in mining at Nome and other outlying parts of Alaska, has for about a year been directing the sinking of two shafts at Morden, near South Wellington, Vancouver island, where the Pacific Coast Coal Mines, Limited, is opening a new coal mine. During the first half of February coal was encountered in the mine shaft, at a depth of 610 ft. A station is being cut so that the mining of coal may soon be commenced. There is stated to occur here a fine bed of good coal, and the shaft is alongside the railway to the company's docks.

Mr. A. B. W. Hodges' contract to remain for three years with the Cerro de Pasco Mining Co., of Lima, Peru, as general manager, expired in February. Mr. Hodges writes that for the next few months he proposes to travel in the United States and Canada, but his permanent address will be P.O. Box 140, Toolele, Utah.

Mr. C. N. Henrotin has resigned the post of superintendent of mines to the Canadian Copper Co. at Copper Cliff, Ont.

At the last meeting of the Council of the Canadian Mining Institute, the following gentlemen were admitted to membership: (Members)—Messrs. John A. Allan, Edmonton South, Alta.; Norman M. Campbell, Montreal, Que.; John R. Cox, Ottawa, Ont.; H. S. Dunn, Jr., Scotland; A. E. Geister, Buckingham, Que.; Thos. C. Gorman, Ottawa, Ont.; A. O. Hayes, Princeton, N.J., U.S.A.; C. B. Kingston, London, E.C., England; Robt. J. Lee, Elcan, Alta.; T. A. MacLean, Ottawa, Ont.; W. W. Mein, New York, U.S.A.; N. C. Pitcher, Lethbridge, Alta.; Chas. F. Rand, New York, U.S.A.; J. A. T. Robertson, Szechwan, China; C. M. Ross, Ottawa; R. S. G. Stokes, New York, U.S.A.; Robt. C. Wallace, Winnipeg, Man. (Associates)—Col. John Carson, Montreal, Que.; The Hon. P. Poirier, Ottawa, Ont.; Paul Rochussen, Vancouver, B.C.

# SPECIAL CORRESPONDENCE

## NOVA SCOTIA

### Dominion Coal Company Outputs.

The corrected outputs in January from the Glace Bay mines of the Dominion Company showed a total of 384,361 tons, comparing with 281,007 tons in January, 1912. The Springhill outputs were slightly smaller than last year, being 30,424 tons against 39,084 tons in January last. The February outputs will approach 360,000 tons at Glace Bay, and 32,000 tons at Springhill, comparing with 330,326 tons and 34,708 tons respectively in February, 1912. The combined outputs for the first two months of the year will be 807,000 tons compared with 685,000 tons in 1912, giving a net gain of over 120,000 tons. The weather conditions have been unusually favourable for colliery operations, but at sea heavy weather has been the rule for nearly three months.

### Barometric Records at Collieries.

The fluctuations of the barometer during the months of December and January were unusually noticeable. The summer of 1912 was accompanied by a persistently low and steady barometer, and there was a marked absence in Nova Scotia of heavy wind and rain storms. Although the summer was cold and apparently wet, the actual rainfall was much below the average, as was evidenced by a pronounced shortage of water. Towards the end of November, however, and in December there were heavy rainstorms accompanied by gales and irregularities of the barometer. On the 27th of December the glass in Cape Breton fell from 30.5 inches to 28.5 inches, apparently the lowest reading in Nova Scotia for many years past. The suddenness of the fall and the low reading reached had a noticeable effect on the ventilation of some of the collieries. The Mines Regulation Act requires that a barometer shall be placed in a prominent position at every coal mine, and records of the reading of the barometer are required to be kept at every colliery by some responsible official. It is difficult, however, to see the real utility of this provision. The mine gases are, of course, a much more delicate index to barometric variations than the most accurate barometer, and the effect of a marked change in the atmospheric pressure is felt in the mine long before it can be noticed on the ordinary barometer. The effect of a change in the atmospheric pressure as felt underground is concerned more with the rapidity of the rise or fall of the barometric index, than with the actual pressure itself. There may possibly be some utility in studying barometer readings if it is possible to forecast a rise or fall, but it is not possible to form any true idea of barometric action from a series of detached readings recorded at some set hour of every day. To study the barometer intelligently there must be a continuous reading, over very extended periods, showing the conditions obtaining before and after every marked variation. For this reason, it is doubtful if any form of barometer outside of a recording instrument, or "barograph" is of any real usefulness at a colliery. The so-called "colliery warnings" issued for many years in the English newspapers are a classic joke amongst mining engineers on the other side. In Canada, however, and the United States, where the continental conditions permit of barometric observations over a large land area, it is possible to form very accurate ideas regarding the tendency of the barometer and the direction of travel of certain barometric zones. This being so, it is conceivable that a colliery manager could so use the telegraphic observations as to anticipate important barometric disturbances and take whatever precautions suggested themselves to him. In Germany telegraphic "warnings" are sent to colliery managers of approaching fluctuations of the barometer, and from the School of Mines at Bochum a warning is also sent out whenever the variation of the magnetic needle is greater than usual.

### Dominion Coal Company Employees Benefit Society.

The report of this Society for the year ending 31st December, 1912, shows that the membership increased from 10,045 members at the end of 1911 to 11.120 at the end of 1912.

The receipts for the year amounted to $144,364, of which $63.485 was received from members, $63,197 from the Dominion Coal Company, $11,455 from the Government of Nova Scotia, and $6,245 from interest on investments.

The expenditure amounted to $98,629, leaving a surplus of $45,735. During the year liabilities were undertaken to the amount of $48,585, and there was paid on account of accrued liabilities the sum of $24,353.

The number of deaths was 70, placing on the funds 40 widows and 89 children. On 31st December, 1911, there were 54 widows and 238 children on the fund, and at the end of 1912 there were 87 widows and 293 children, an increase during the year of 33 widows and 55 children.

The payment of $98.629 included $68.910 paid in weekly indemnity to members disabled either by accident or sickness, $7,629 on account of death claims and $16,723 paid to widows and children of deceased members.

The gross assets of the Society amounted to $183,001. The sum of $125.000 is set aside as a reserve to meet liabilities incurred. The net surplus at the end of 1912 is shown as $50.501.

At the end of 1912 the Society had completed two and one-half years of its life, and shows very satisfactory progress in so short a space. The membership includes practically all the company's employees in Cape Breton, and has grown from a little under 7.000 in 1910 to the present figure. A further increase in the membership may be forecasted for 1913. An encouraging feature is the growing income from investments, which now more than pays the expenses of administration. As the payment to widows extends over five years, and the payment to children up to the age of fourteen years, the Society has not yet experienced its maximum liabilities.

---

## ONTARIO

### LARDER LAKE.

Goldfields, Limited, of Larder Lake, announces its intention of adding another thirty stamps to its mill, which according to computation will raise its capacity to 500 tons per day. At present there are thirty stamps dropping, but as the mill is of the simplest description the duty per stamp will probably not be very high. Goldfields, Limited, was formed to take over the Harris Maxwell, The Proprietary, and the Tourneninie (Old Indian) properties. The company secured control of these two latter properties after they had gone into liquidation, but only the Harris Maxwell is now being worked. The outcrop of the ore body has been stripped on a rise about 100 feet above Larder Lake, the mill and the rest of the plant being at the foot of the hill and the ore body cut at a depth of 65 feet. The ore body as it is at present defined is about 115 feet long by about 15 feet wide, and raises are being made through to the surface in several places. The company has a power plant at Raven Falls where there can, if necessary, be generated 15,000 horse power. Everything in the mine is electrically driven including the twelve-drill compressor.

### PORCUPINE.

The developments on the McEnaney in Porcupine have been so remarkable that it has been determined to erect a twenty stamp mill with cyanide plant as soon as any addition is made to the five-stamp mill already in operation. The five stamps are at present dropping on forty tons of ore per day. Ore is being taken from the drift on the vein at the second, third and fourth level. It is the progress being made at the fourth level that has surprised the management. When the vein was first cut there was a sixth foot width of $48 ore. That is the biggest ore body and the highest grade yet found in the mine where every level opened has proven better than the one above. This level has been developed for about 30 feet and in the face now there is eight feet of ore running between $30 and $40 with a continuous ore body from the cross-cut. The growth of the McEnaney from a poor prospect to a remarkable mine in one year has been the feature in Porcupine within the last six months.

### KIRKLAND LAKE.

From the Tough claims at Kirkland Lake on an open cut 35 feet long there has now been taken 52 tons of ore which will average over $500 to the ton. No considerable depth has been attained yet and the deposits may be very shallow, but it has been demonstrated that the ore in sight can be taken out with good profit and that the insignificant veins on the surface may develop into fair ore bodies below. The most encouraging feature of this remarkable property is that each successive shipment from the property has been richer than the preceding one.

There is now being collected at Swastika a thirty ton shipment of ore which will exceed any consignment of crude gold ore that has left the north country.

### GOWGANDA.

The Mann at Gowganda has pushed its drift over the boundary into what was once Boyd Gordon territory and has taken out enough ore to pay back in full the entire price paid for the property.

The Boyd Gordon had a rather spectacular silver showing on the surface and was sold by Al Boyd and his associates for a long price. The purchasing company went to work at a tremendous expense, but it appeared to be merely silver plated as values soon disappeared as the shaft was sunk.

Then the Mann, owning the adjoining properties opened up the claim and began to develop. So encouraged were the Mann owners with what they found that they approached the Boyd Gordon Company for the purchase of the latter property. The directorate of the Boyd-Gordon had given up real hope and were glad to get anything that looked like real cash and the deal was closed for a sum said to have been in the neighborhood of $8,000. The Mann developed the vein right up to the Boyd-Gordon property and followed it over the line. Already the Mann has yielded enough ore to cover the purchase of the property.

### COBALT.

The Cobalt Lake fault the Right of Way is now developing to discover what prospects it has of getting ore along the contact. Although, of course, it is not known where it will be struck the management expects to strike it 350 feet below the surface or 200 feet below the level they are working at present. The new ore body which was recently found at the first level has been drifted on as far as the La Rose boundary where it was strong and of high grade ore. In all the Right of Way had about 32 feet of it. The vein for that distance averaged two and a half inches of ore that ran between 1500 and 2000 ounces. The vein has not been picked up on the second level yet, but a shaft has been put down.

After five years of litigation the law suit between the Bailey Cobalt Mining Co. and the Cobalt Central Mining Co. has been settled. $31,000 was the amount awarded the Bailey Cobalt and the long legal fight is over. The action was first brought by the Bailey Cobalt Mining Co. against the old Cobalt Central, but that organization went into liquidation and the liquidators have been waging the fight ever since.

The case dates back to 1907 when the old Cobalt Central was the most advertised producer in the camp and had a higher place on the stocks of the New York Curb than Nipissing. The management of the Cobalt Central discovered that a goodly part of the ore body was close to the Bailey line and made overtures to that company to mine the ore on a royalty basis. The Cobalt Central was to pay all expenses and deduct the same from the gross receipts, the two companies to share equally in the proceeds.

When the time for the Central to make a settlement came a dispute was raised as to the exact location of the line between the two properties the Central claiming a plot of territory and the Bailey disputing.

## BRITISH COLUMBIA

The pamphlet, "Preliminary Review and Estimate of Mineral Production, 1912," issued in January by the Provincial Department of Mines, has been in such demand that it has been found necessary to have one thousand more copies printed, the larger supply at first provided having been exhausted.

**Dividends from Metal Mining.**—The year 1913 has witnessed an encouraging beginning in dividend payments by mining companies operating metalliferous mines in the province. The Standard Silver-Lead Mining Co. paid dividend No. 10 on January 10, and No. 11 on February 10, each of $50,000, being two and a half per cent. a month, or at the rate of 30 per cent. per annum. The company made its first distribution of profits in April, 1912, of $25,000, and has since divided $50,000 each month, so that the distribution as at February 10 brought the total of dividends to that date up to $525,000 on an issued capital of $2,000,000. On January 15, the British Columbia Copper Co. distributed $88,756.35, being at the rate of 15 cents a share on its 591,709 issued shares. The Granby Consolidated Mining, Smelting & Power Co. has declared a dividend of $1.50 a share, payable March 1; as at the date of its last annual report the company's total of issued shares was 149,985, this involves a distribution of $224,977.50. The total of dividends to March 1, inclusive, will, therefore, be $413,733.85. On February 8, the Engineering and Mining Journal, New York, included in its list of January dividends, Le Roi No. 2, Ltd., 36 cents a share, total $43,740, but pending confirmation from Mondon, this is not included in the aggregate of dividends to March 1, above given.

**A Complicated Case.**—The Vancouver Daily Province published on February 15 the following: "One of the most complicated cases before the courts for some time was opened yesterday before Chief Justice Hunter, in which the British Columbia Copper Co. is suing E. M. McKittrick, of Indiana, and H. C. Kerman (sheriff), J. S. Birnie (registrar of court at Greenwood), and C. J. Leggatt, a solicitor.

The suit arises out of the death of G. C. McKittrick at one of the mines of the company in Boundary district, on May 28, 1910. The Miners' Union put in a claim for compensation on behalf of McKittrick's father, who resides in Indiana. The claim was referred to the county judge at Greenwood to arbitrate. The Ocean Accident and Guarantee Co., which insured the British Columbia Copper Co., after negotiations with Mr. Kittrick, Sr., in Indiana, obtained from him, for a sum of $250, a release of his claim. After obtaining this release, they notified Mr. Leggatt, who was prosecuting the claim for compensation on behalf of McKittrick at the instance of the Miners' Union. Mr. Leggatt ignored the settlement and succeded in getting an award of $1,500 from the arbitrator and proceeded in due time to take out an execution against the British Columbia Copper Co. for the amount of the award, though warned by the company's solicitors that they would hold him liable for damages. Under the execution, Mr. Leggatt and his co-defendants garnisheed monies due to the British Columbia Copper Co.

The suit before the court now is for an injunction to restrain the defendants from exercising the execution, a declaration that the award of the arbitrator be set aside, a claim for $2,000 damages for the loss of interest on the monies tied up by defendants on the garnishee proceeding and general damages.

The principal defence is that the plaintiffs did not attend the arbitration and produce evidence to show that any settlement with McKittrick had been arranged. The outcome of the case is being looked forward to with much interest by miners of the interior of the province.

**East Kootenay.**—The Consolidated Mining and Smelting Co. during January shipped about 3,600 tons of lead-ore from the Sullivan Group mine to its smelting works at Trail. Much exploratory work having been done in new ground last year, an enlarged production of ore is looked for in 1913. Operations at the company's St. Eugene mine are now on a much smaller scale than in past years, but there is still a small production of ore being maintained.

At the several collieries in Southeast Kootenay, coal-mining is generally active, although occasionally the output is unfavourably affected by a shortage of railway cars. One colliery—that of the Corbin Coal and Coke Co., of Spokane, Washington—with coal mines situated about 14 miles south of McKillivray, a station on the Canadian Pacific Railway Co.'s Crow's Nest Railway, is preparing to mine coal open-cast, having cleared off the surface debris from a considerable area so as to allow of the big deposit of coal, occurring almost at the surface and proved to be fully 300 ft. wide, being worked as an open quarry. It is proposed to use a steam-shovel to take the coal direct from the face and load it into railway cars.

**West Kootenay.**—Deep snow has interferred somewhat with mining operations in Ainsworth and Slocan divisions, though mines situated near one or other of the lakes have not had similar transportation difficulties to those experienced by mines in the midst of the mountains. The Bluebell, near Kootenay lake, and the Standard and Van Roi, near Slocan lake, have kept up their respective outputs with little or no diminution. The Rambler-Cariboo and Ruth-Hope have also made shipments, though on a smaller scale. It is expected that the former of these two will this year produce much more ore than in earlier years, for it now has much improved transportations facilities, an aerial tramway having been constructed from the mine down to the concentrating mill recently completed alongside a newly-finished branch railway line. Near Sandon, deep-level development is being continued at the Slocan Star and Payne mines, but snow slides and accompanying winter difficulties have made it necessary to suspend work for the time at several mines in the vicinity of Cody. The Lucky Jim mine, situated on the divide between Slocan and Ainsworth divisions, and the Retallack & Co. and Utica mines, on the Ainsworth side of the divide, are among the operative mines of this part of West Kootenay district.

In Nelson division, the British Columbia Copper Co. is continuing development of the Eureka copper mine, under option of purchase, and is shipping copper ore from the Queen Victoria mine, purchased last November, to its smelting works at Greenwood. The Kootenay Gold Mines, Ltd., is endeavouring to obtain additional capital for the purpose of doing needed development work, so as to keep its 20-stamp mill regularly running. The Consolidated Mining and Smelting Co.'s Molly Gibson silver-lead mine is also one of the ore shippers of this division. In Ymir camp, development work is being continued at the Wilcox and Dundee mines. Near Salmo, the Emerald and H. B. are shipping lead-ore. Gold ore is being crushed at the respective stamp mills of the Mother Lode and Queen, in Sheep Creek camp, and of the Second Relief, in Erie camp, while the Arlington, also at Erie, is being worked under lease.

Rossland mines made a production of about 23,000 tons in January, of which 13,000 tons was from the Consolidated Co.'s Centre Star-War Eagle group, 7,000 tons from its Le Roi mine, and 3,000 tons from the mines of the Le Roi No. 2, Ltd.

**Boundary and Similkameen.**—The big copper mines of Boundary district are maintaining their normal output of ore. The largest producers were the mines at Phoenix of the Granby Consolidated Co., the British Columbia Copper Co.'s Mother Lode coming next, and the New Dominion Copper Co.'s Rawhide mine being third, while several small mines also added to the total production for January. The British Columbia Copper Co.'s new general manager, Mr. Oscar Lachmund, has been in local charge for several weeks. No information is yet available concerning the company's future operations in Similkameen district, but it is known that the Hedley Gold Mining Co., operating in Hedley camp, continues to crush about 6,000 tons of gold ore a month and to make good profits.

**Coast District.**—The Britannia, near Vancouver city, and the Granby Co.'s Hidden Creek mines, in the vicinity of Observatory inlet, are doing the chief development work in connection with metalliferous mining on the British Columbia coast. The Marble Bay mine, on Texada island, in which bornite ore has been mined down to a depth of 1,000 feet, is now being opened at about 1,100 feet vertical depth.

Important developments are taking place on several coal-mining properties on Vancouver island. The Western Fuel Co., of San Francisco, has already spent $500,000 in connection with the opening, equipment, and transportation facilities of a new mine within five miles of Nanaimo. The Pacific Coast Coal Mines, Ltd., has lately reached coal in a new shaft, at 610 feet from the surface. The Canadian Collieries (Dunsmuir), Limited, is also opening a new mines, this being in Comox district, farther north on Vancouver island than the other properties previously mentioned.

Altogether, the outlook for mining in the Coast district of British Columbia is promising, and a larger all round production in 1913 is expected.

# COMPANY NOTES

### CALMET AND HECLA.

A quarterly dividend of $10 a share was declared by the Calumet and Hecla Mining Company on February 20th.

### THE ENGLISH COBALT LAKE COMPANY.

Under the title of the Cobalt Lake Silver Mining Company, Ltd., a company was registered on January 21st with a capital of £300,000, in £1 shares, to carry on the business of silver and general miners, prospectors, explorers, metallurgists, etc., and to acquire and deal with any mines, mining rights and metalliferous lands in Canada or elsewhere. The signatories are: J. E. Way, 36 Waveney Avenue, Peckham Rye, S.E.; C. H. Perry, 62 Ainslie Wood Road, Chingford; J. H. Jones, 212 Totterdown Street, Tooting, S.W.; H. H. Piddington, 10 Heron Road, Herne Hill, S.E.; H. C. Allaway, 15 Blucher Road, Camberwell, S.E.; A. T. C. Warbey, 57a High Street, Kingsland, N.E.; W. T. Bond, 6-21 Cranworth Gardens, Brixton, S.W. (one share each).

Minimum cash subscription, seven shares. The first directors (to number not less than three nor more than seven) are to be appointed by the signatories. Qualification £200. Remuneration, £100 each per annum (Vice-Chairman, £150). Registered office, Balfour House, Finsbury Pavement, E.C.—Exchange.

### SENECA-SUPERIOR FIRST ANNUAL MEETING.

The first annual meeting of the Seneca-Superior Silver Mines, Limited. was held in Toronto on February 15th. Total production since the early part of October of just under $200,000 worth of silver and net profits of $121,618 are shown in the annual report. Out of these profits a ten per cent. dividend was paid of $47,683, leaving a surplus on January 31st of $73,980.

Mr. R. H. Lyman, mine manager, in his report, stated that the Worth vein, which was discovered early in October, has been developed for 213 feet, and has shown an average value of 3,500 ounces to the ton for this distance. The cross-cut has been continued to 174 feet beyond this vein. and will be continued to the southeast shore of Cart Lake.

Mr. W. E. Segsworth, consulting engineer, said that it was hoped this cross-cut would disclose other producing veins. During development an area of 2,500 square feet on the vein has been broken, and the ore produced is estimated to contain about 310,000 ounces of silver. Mr. Segsworth estimates that this development has put in reserve about 1.150,000 ounces of silver.

The following directors were elected for next year: Messrs. F. H. Worth President), A. H. Dewey, F. W. Zoller, W. E. Segsworth, and R. F. Segsworth.

### HOLLINGER DIVIDENDS.

The dividends of the Hollinger mine. with the declaration to be paid February 18th, will reach nearly a half million dollars and that mine, with its four weekly basis, is as yet the only property to establish a regular dividend payment. The dividend payable this month will disburse $90,000, like the previous ones. It makes a total of 15 per cent. and $450,000 paid.

The payments to date follow:

| | P.C. | Amount. |
|---|---|---|
| 1912—November 2 ........ | 3 | $90,000 |
| November 30 ........ | 3 | 90,000 |
| December 30 ........ | 3 | 90,000 |
| 1913—January 28 ......... | 3 | 90,000 |
| February 3 ......... | 3 | 90,000 |
| Totals ..................... | 15 | $450,000 |

### CROWN RESERVE MINING COMPANY.

Notice is given that a dividend of 2 per cent. for the month of February, 1913, and bonus of 3 per cent., for the same period, making a total payment of 5 per cent., has been declared and will be payable on the 15th March, 1913, to shareholders of record the 28th February.

### COBALT LAKE MINING COMPANY.

The annual general meeting of the Cobalt Lake Mining Company was held in Toronto on February 26th.

### COBALT TOWNSITE CABLE.

Estimated results for week ended 25th January: "Value of production, £4,773; operating expenses, £1,738; weekly profit, £3,035."

### DOMINION MINISTER OF MINES.

At the annual convention of the Conservative Association of British Columbia, held at Revelstoke, B.C., a few weeks ago, and largely attended by delegates from many widely-separated parts of the province, among the resolutions presented for endorsement by the convention was one favouring the appointment of a Dominion Minister of Mines. The resolution was presented by delegates from Nelson, B.C., but in committee was altered at the persistent request of Mr. E. Jacobs, so that as presented to the convention and adopted it read as follows:

"That, whereas the mining industry has become one of the most important in the Dominion, having attained a production of $102,291,686 in the year 1911; and

"Whereas the value of the mineral production of Canada has shown a steady growth in having risen during the last decade from $63,231,836 to the first above-mentioned sum; and

"Whereas the further development of the whole mining industry of the Dominion of Canada can be materially aided by greater attention being paid to its requirements and possibilities; and

"Whereas the Canada Department of Mines is at present under the control of the Minister of the Interior, the work of whose department is so heavy that he cannot give to the Department of Mines the attention its great importance demands,

"Therefore be it resolvel, that in the opinion of this convention it is urgent that there be a separate Minister of Mines who will be free to give this department the attention essential to the further development of the mineral resources and the best interests generally of the mining industry of Canada."

### DRILL FOR CUTTING SAMPLES.

Cnting samples in a mine where the ore is hard, tough, compact quartzite, such as is the banket ore on the Rand, or similar material, is a laborious task, often requiring half an hour per foot of sample. Mr. Noel Griffen has described in the Journal of the Chemical, Metallurgical and Mining Society of South Africa a method by which a small chipping hammer, not unlike a pneumatic rivetter adapted for carrying a cutting bit, can be used, greatly facilitating the cutting of mine samples. The chipping hammer recommended is an Imperial, size B, No. 1, weighing 10½ pounds. A rose bit 2 inches in diameter has been found preferable to any other shape. The clippings and dust are caught in a canvas bag, supported in an open position by a stiff wire or round iron frame, and measuring about 24 by 18 inches, so arranged that the drill bit can be passed through a hole in the bottom of the bag, the opening being reinforced by two washers to prevent tearing at the edge. The bag is held against the face and the bit directed by the left hand, while the handle of the drill is grasped by the right hand so that the controlling trigger can be operated by the right forefinger. The drill requires ½-inch air hose. It is stated that at first the drill is difficult to control, but after a few days' practice the operator becomes proficient enough to cut a channel 2 inches wide and ½ inch deep across the face of a drift at the rate of 2 feet in ten minutes in the hardest rock. The work requires much muscular exertion, but in tough ground far less exertion is required to cut a sample by machine than by hammer and moil. The rock cut out by the rose bit ranges from powder to chips half the size of a pea, so that if any larger pieces flake off beyond the edges of the desired channel they may be readily removed by screening. It is said that if the drill is held well up against the face the chips do not fly as much as when sampling is done by hammer and moil.

# STATISTICS AND RETURNS

### BUFFALO MINES FOR DECEMBER.

Buffalo Mines, Ltd., reports for December: Mill ran 582 hours, ore milled 4,616 tons; average assay portion before milling 44.16 ounces; silver recovered 178,371 ounces and silver paid for during month shipped previously 33,179 ounces.

### HILLCREST COLLIERIES.

From Hillcrest Collieries, Limited, is reported steady progress at the property and the demand for the company's coal is excellent. The progress made in the past two years may be seen by the comparative figures for January 1913, 1912, and 1911, as follows:

| | |
|---|---|
| Jan. 1911 | 8,375 tons |
| Jan. 1912 | 11,805 tons |
| Jan. 1913 | 17,800 tons |

The new plant is proving satisfactory. The annual meeting will be held March 4th.

### DOMINION STEEL JANUARY OUTPUT.

The output of the Sydney plant of the Dominion Steel Corporation, Limited, for January was as follows:

| | |
|---|---|
| Pig iron | 27,164 tons |
| Steel ingots | 28,022 tons |
| Blooms | 25,809 tons |
| Rails | 14,410 tons |
| Wire rods | 3,092 tons |

The coal output in the Cape Breton collieries for the month was 414,944 tons, as compared with 320,091 tons in 1912.

### McKINLEY-DARRAGH IN JANUARY.

During the month of January the McKinley-Darragh Savage mines produced 180,000 ounces the cleaning-up process, which is the rule at most of the mines in the camp, cutting down the tonnage somewhat. Owing to the very heavy program of development at the Savage, and the alterations proposed to the plant there, the Savage only contributed 20,000 ounces.

### B. C. ORE RECEIPTS.

The Consolidated Mining & Smelting Co., of Canada, Limited, ore receipts at Trail Smelter for the week ending February 1, and from July 1 to date, in tons:

Company's mines:

| | Week of Feb. 1 | July 1 to date |
|---|---|---|
| Centre Star | 2,568 | 93,835 |
| Le Roi | 1,579 | 27,081 |
| Sullivan | 720 | 17,975 |
| Molly Gibson | 128 | 1,277 |
| St. Eugene | ..... | 801 |
| Richmond-Eureka | ..... | 778 |
| No. 1 | ..... | 153 |
| Other mines | 1,371 | 45,643 |
| Balance | 6,366 | 187,543 |

### VAN ROI.

Cable:—"Mill report for December: Total amount crushed, 3,334 tons (average assay 8.9 ozs. silver, 2.5 per cent. lead, 5.0 per cent. zinc), yielding 106 tons lead concentrates, assaying 129.9 ozs. silver, 56.5 per cent. lead, 14.3 per cent. zinc; and 124 tons zinc concentrates, assaying 42.0 ozs. silver, 3.7 per cent. lead and 44.0 per cent. zinc. Mill ran 596 hours. Total approximate value, $12,557 (£2,589). Estimated expenditure for corresponding period—Development $2,195, ore production $11,796, milling $3,200—$17,191 (£3,544). Capital expenditure, $203 (£42). Westward drift, level 7—Breast is 1,453 feet west of portal. Advance 118 feet driven. Promising. Westward drift, level 9—Breast is 1,338 feet west of portal. Advance 74 feet driven. Promising. Drift eastward—35 feet up. No. 3 intermediate raise above level 2—Advance 32 feet, of which 25 feet averaged 20 ozs. silver, 4 per cent. lead, 5 per cent. zinc, across 6 feet."

## MARITIME COAL SHIPMENTS.

**Coal Shipments, January, 1913, Dominion Coal Co., Ltd.**

Output and shipments for January, 1913:

| | Output. | Shipments. |
|---|---|---|
| Dominion No. 1 | 44,788 | |
| Dominion No. 2 | 65,793 | |
| Dominion No. 3 | 11,042 | |
| Dominion No. 4 | 32,549 | |
| Dominion No. 5 | 20,901 | |
| Dominion No. 6 | 20,322 | |
| Dominion No. 7 | 18,185 | |
| Dominion No. 8 | 8,255 | 267,795 |
| Dominion No. 9 | 33,144 | |
| Dominion No. 10 | 19,091 | |
| Dominion No. 12 | 27,972 | |
| Dominion No. 14 | 30,241 | |
| Dominion No. 15 | 17,277 | |
| Dominion No. 16 | 18,973 | |
| Dominion No. 21 | 13,089 | |
| Dominion No. 22 | 2,749 | |
| | 384,361 | |

| | |
|---|---|
| Shipments, January, 1913 | 267,795 |
| Shipments, January, 1912 | 186,346 |
| Increase, January, 1913 | 81,449 |

**Springhill.**

| | |
|---|---|
| Shipments, January, 1913 | 22,003 |
| Shipments, January, 1912 | 28,732 |
| Decrease, January, 1913 | 6,729 |

| | |
|---|---|
| Shipments, January, 1913 | 21,960 |
| Shipments, January, 1912 | 22,679 |
| Decrease, January, 1913 | 719 |

**Acadia Coal Co.**

| | |
|---|---|
| Shipments, January, 1913 | 40,539 |
| Shipments, January, 1912 | 30,964 |
| Increase, January, 1913 | 9,575 |

## COBALT ORE SHIPMENTS.

The shipments from the Cobalt camp for the week ending February 15, amounted to 332.25 tons from nine members. But two of these shipments were of low grade ore. The bullion all went out in one day, on Tuesday, and constituted a record for the camp and probably for the Dominion, three mines shipping about $190,000 in silver bars. Shipments were as follows:

| Mine. | High. | Low. | Tons. |
|---|---|---|---|
| Cobalt Lake | 1 | .. | 39.00 |
| Peterson Lake (Seneca-Superior lease) | 1 | .. | 31.75 |
| Drummond | 1 | .. | 42.10 |
| Nipissing | .. | 1 | 42.00 |
| McKinley-Darragh | 2 | .. | 59.27 |
| Hudson's Bay | 1 | .. | 30.70 |
| Coniagas | 1 | .. | 24.24 |
| La Rose | 1 | .. | 32.94 |
| Beaver | 1 | .. | 30.25 |
| | 9 | 1 | 332.25 |

**Bullion Shipments.**

| Mine. | Bars. | Ounces. | Value. |
|---|---|---|---|
| Nipissing | 176 | 214,206 | $132,807 |
| Crown Reserve | 15 | 15,691 | 9,354 |
| Dominion Reduction | *72 | 79,200 | 45,405 |
| | 263 | 308,997 | $187,567 |

*Estimated.

## LA ROSE MINE IN JANUARY.

The January statement of La Rose is not quite as good as the preceding month.

Production for January was 219,977 ozs., with a value of $134,724. This plus a sundry income of $3,741, gives a total income for the month of $138,465. From this amount is deducted $62,187 for market expenses, etc., leaving January profits of $76,278.

The cash surplus totalled $1,324,290, plus outstanding shipments of $229,978 or a total of $1,548,268.

Ore on hand ready for shipment totals $53,913.

The total cash surplus stands at $1,602,181.

The actual cash surplus on December 31, 1912, was $1,667,104.

## NIPISSING IN JANUARY.

During January, Nipissing mined ore of estimated net value of $204,780, and shipped ore estimated at $170,377 net. The decrease in the shipments is due to the annual clean-up at the high grade mill. At 20 feet of milling ore is being opened up. Shaft 64 has reached a depth of over 560 feet, and in 100 feet station will be cut.

## B. C. ORE SHIPMENTS.

Week ending February 8th.

| | Week. | Year. |
|---|---|---|
| **Boundary.** | | |
| Total | 36,428 | 193,887 |

| Total | 359 | 359 |

## B. C. ORE SHIPMENTS.

Week ending February 15.

What was probably the first shipment of ore sent out from the north of the province over the new Grand Trunk Pacific Railway line to Prince Rupert was smelted last week at the Consolidated Mining & Smelting Company's plant at Trail. The ore came from the Silver Standard mine at Hazelton, a property owned by J. W. Stewart, of Foley, Welsh & Stewart, and partners. From Prince Rupert the ore was shipped by steamer to Vancouver and then brought to Trail over the Canadian Pacific line.

Four properties in Kootenay were added to the year's shipping list during the week. They were the Lily B., Fidelity, Nickel Plate, and Hope.

Ore production in the Kootenay and Boundary districts last week totalled 47,764 tons, and for the year to date 309,606 tons. Smelter receipts for the week ending February 15 were 42,101 tons, and for the year to date 263,163 tons. Production in detail was:

### Boundary.

| | Week. | Year. |
|---|---|---|
| Granby | 24,546 | 139,800 |
| Mother Lode | 5,520 | 41,955 |

# CANADIAN MINING INSTITUTE.

By J. C. MURRAY

A national organization that has an active membership of more than 1,000, including technologists and business men of all grades from the professor to the promoter, from the geologist to the prospector, from the managing engineer to the investor, is bound to exercise large influence on the country's life. The Canadian Mining Institute is not only national; it has important international connections and affiliations. Its members are distributed all over the world. Its publications reach South America, Asia, Europe, Africa, and Australia, beside having wide circulation in Canada and the United States. Hence they are uniquely valuable media for the dissemination of information. Official correspondence is maintained with representative foreign members, and the accounts of the annual meetings reach every important country in the civilized world and many remote mining districts.

The annual meetings have been, and are, remarkably interesting in character. Professional papers, the cream of current technical thought, historical and economic treatises, are read and discussed. Important questions of trade, of politics, and of ethics are debated, and wide publicity is given to the Institute's resolutions. At the social functions that are part of the annual proceedings, to wit, the dinner and the smoker, the nation's leading legislators and officials are honoured guests. The smoker, by the way, has developed into an outstanding event. Free rein is given the reckless ingenuity of certain members, and the results are often amazing. Honoured, if somewhat irregular and unconventional customs, mark the evening of the smoker. It is unnecessary to expatiate upon these. The arcana of the Institute when it "stands easy" need not be explained. Each member must learn for himself.

The Institute is much more than a technical society. It is a brotherhood. In a mild way, masonry is its archetype. The isolated mining man can count upon at least one annual foregathering with his fellows and his friends. He comes, therefore, to the place of meeting determined to learn what he can, to have a thoroughly good time, and to take his part dutifully in the proceedings. During the three days he meets friends, old and new; rubs elbows with novices and notabilities, hears speeches excellent and otherwise, keeps reprehensibly irregular hours, and leaves refreshed, inspired, and ready for another long year of labour. How much good he receives cannot be estimated; but it is beyond doubt that the atmosphere of the convention is charged with beneficent influence. The man who is not responsive or receptive has only himself to blame.

Unlike other professional societies, the Canadian Mining Institute is neither a close nor an exclusive corporation. Although to attain full membership the applicant must show that he has had ample experience in some branch of mining, and although these requirements have been made more rigid of late years, yet associate membership is open to the non-technical of all kinds and degrees.

Hence there exists in the ranks of the Institute, particularly as represented at the annual meeting, a very profitable variety of human types and human attainments. The lawyer, the investor, the prospector, the metallurgist, the organizer, the journalist, the geologist, the chemist, the mine manager, the government official, all will be present at the forthcoming meeting in Ottawa. This condition is, naturally, most desirable. The diversity of men and manners imparts zest to the proceedings.

It is obvious that the Canadian Mining Institute possesses, consciously or unconsciously, decided powers for good. That these powers are exercised wisely goes without saying. That they should be more profoundly felt is axiomatic. The Institute has achieved solidarity socially, but not yet in a political sense. The necessity for such solidarity is too apparent to require demonstration. While it would be destructive and futile to interfere with party politics, yet the Institute must be prepared effectually to face certain grave and critical situations. Such a situation exists at the present moment.

The functions of the Institute are many. It is called upon to express itself on questions of legislation and administration. It plays an important part in receiving and entertaining foreign delegations. In fact, the Institute is the only suitable organization for purposes of this kind. We have touched already upon its publications and its social aspects. These are all vital. But in themselves they are quite subordinate to the duty of safeguarding the mining industry. Occasions arise when it is imperative that the Institute be not only heard, but felt. Wise guidance, long deliberation, and dignified action are essential. Recognition of the fact that individually and collectively the members of the Institute can exercise large influence on the electorate is even more essential. That such influence, largely formative, and educational, should be exercised, implies nothing invidious. It were weak and foolish to blink facts. The Institute cannot confine itself merely to the formulation of protests. It should and must use every legitimate means to attain its legitimate ends. In fact, the

# PORTRAITS, NEW AND OLD—MOSTLY OLD

THE LATE B. T. A. BELL,

Parent of the Institute. He made history. His works do follow him.

T. W. GIBSON,
Deputy Minister of Mines for Ontario.
This is from a Victorian Photograph.

HON. L. CODERRE, Minister of Mines.

A. P. LOW, Deputy Minister of Mines.

Paleozoic Picture of Mr. Low.

Institute must take itself seriously as a factor in the national life of Canada.

And this rests but in small measure with the Secretary and the Council. Every member must put his shoulder to the wheel. The thoroughly concerted action of one thousand responsible Canadian citizens should be adequate for the attainment of almost any object within the scope of the Institute's activities.

. . . . .

In both the territorial and the class sense the Institute is representative. Every Canadian province sends delegates to the annual meeting. The membership embraces men of all shades of opinion, of all grades professionally, and of many nationalities. Canadians form, of course, the preponderating majority. But Americans, Englishmen, Germans, and others, are sufficiently numerous to leaven the mass. In any movement of a serious nature, in any crisis, therefore, the Institute can count upon the disinterested advice of eminent outsiders. Thus the Canadian Mining Institute is most fortunately constituted. Its functions, while largely deliberative and social, are also administrative and executive. From its size and its composition it commands respect.

The time has arrived for the Canadian Mining Institute to undertake resolutely the solution of national problems. Closer identification with the industry and a more active participation in legislative affairs are crying needs.

. . . . .

I had really intended to make this short article a constructive appreciation of the work of the Institute. The editorial habit of mind, however, is painfully didactic. Apparently the editor lives, moves, and has his being in constant fault-finding and preaching. It is easy to be captious. It may not be amiss, therefore, to take this opportunity of expressing warm appreciation of the labours of our President, our Councillors, and, by no means least, of our Secretary. Our President and Councillors devote time, energy, and, often, money, to the performance of their regular duties—duties that are not in the least nominal. The Secretary, despite his passion for drawing on us for unpaid fees, meets the multifarious calls upon his time with tact and patience. He must, perforce, act like a regular "harumphrodite"—soldier and sailor too. He is editor, advance agent, treasurer, organizer, traffic agent, entertainer, and many other things to all men. Only once or twice a year is it permitted him to have a really good time. Not more than a baker's dozen of us can recall having heard the Secretary raising his voice in midnight, or matutinal song. His is not a cheerful life. Yet he smiles and smiles—and signs certificates, and argues with recalcitrant geologists, and bothers the life out of you and me for our perennial fees and our long-promised papers.

Verily we have a superfine lot of Councillors and an exceeding patient and decent Secretary. How they all get along with so few feuds and internecine wars is not for me to say. The roots of sin and the lust of battle are there. But the balance of power is rarely disturbed. Institute affairs come first, and personal ambitions a distant second.

. . . . .

In every natural organism there are forces at constant war each with the other. Our bodies are the battlegrounds of numberless bacilli, bacilli benign and bacilli malign. Much of the good that we accomplish is brought about by the antagonism of evil. The analogy carries. The Institute has in its time been rent asunder by factions and parties. Toronto and Montreal were at daggers drawn for years. Better feeling was engendered. Epics could be written of encounters between such doughty warriors as Coste and Brown, Haultain and Porter, and other equally warlike personages. Elections have often come within measurable distance of black eyes. Sectional fights to a finish were numerous. Whether because of lassitude, or of waxing dignity, or of a better general understanding, these disturbances appear to be things of the past. Such finished diplomats as Miller, Adams, and Smith, no longer think it worth while to stir the fighting blood of the Institute. It cannot be said, however, that there is any lack of pugnacity and good clean love of battle. Petty jealousies have disappeared. There remain many potent influences that require harnessing and direction. The leaders of the Institute will find no difficulty in utilizing these forces in constructive work for the good of the mining industry. A grand destiny awaits the Institute if we but wake in time.

. . . . .

A sister society, of which many of us are members, has just passed through a trying, and disturbing experience. That the Canadian Mining Institute has enjoyed several years of practically unbroken peace is much to the credit of our Councillors, our Presidents, and our Secretary. It speaks volumes for the manner in which the affairs of the Institute are administered.

## THE PORTRAIT GALLERY

The portraits that appear herewith cover many years of the Institute's history. They include officials old and new. Reference to the Institute's published list will throw more light upon the standing of each. It may be added that the size of each portrait has been determined by quite arbitrary circumstances.

# TO THE INSTITUTE

Such doggerel as this, I trow,
Should not be printed in the Journal;
It surely merits here and now
Condignest torment, sempiternal!

. . . . .

From many countries, many climes,
The sons of Martha hasten here,
Each big with much unspoken thought,
Each filled with much unspoken fear
That he will miss the smallest jot
Of what is done or what is not.

. . . . .

Here comes from the metropolis
The gladsome Barlow, who, surprised
And captured the acropolis
Of long ambition realized.
Comes also Miller from the west—
Observe the twinkle in his eye.
His pose of a misogynist
Is not convincing by-the-bye.
And who is this with suavest smile,
Restrained, impersonal, and bland,
As one that you might know long while
Ere you could diagnose his hand?
That, that is Adams of McGill,
The man who made hard marble flow,
And, though we cannot cherish ill,
He treated us precisely so.
And who comes next, dark-visaged, gloomy,
Unsmiling, capable, and cold,
His countenance presaging doom, he
Looks ripe for action swift and bold;
None other this than Bonsall Porter
That most resourceful child of guile,
In politics a rip-tailed snorter
With many a trick and many a wile.
Hard after him there follows smiling
A brisk and truculent confrere;
His manner sharp and not beguiling,
Like—well—a tiger in his lair.
Haultain it is, there's no mistaking
His attitude on anything;
His thirst (for rows) there is no slaking,
His praises students many sing.
There follows one with brow so high
It runs back nearly to his collar;
'Tis A. A. Cole, who's passing by,

DR. W. G. MILLER.
Recent alterations give this picture merely historic value.
Mr. Miller has been ever the power behind the Throne.
Notice the Machiavelian expression.

DR. A. E. BARLÓW.
A poor portrait of our respected President.

CHARLES FERGIE.
Pre eminent in wrestling circles.
Not unknown as a coal
mining engineer.

FREDERIC KEFFER, Past-President.
A thoughtful, benign and conciliating person.

R. R. HEDLEY,
who looks, and is, a good citizen.

A. B. W. HODGES,
lately returned from Cerro de Pasco.

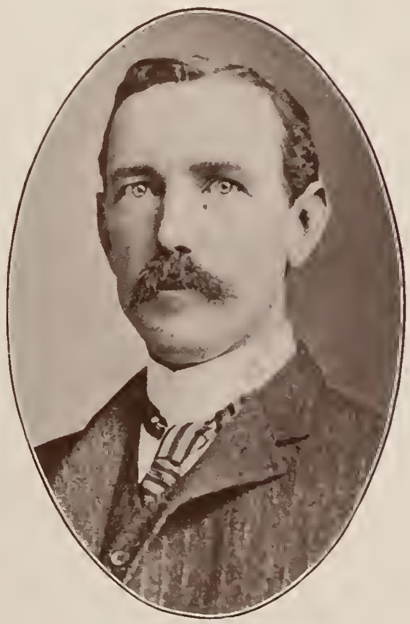
Calm, self-contained, when others holler.
Bull-throated Foghorn next I view,
A child of nature, surely;
Moreover, it is just and due
To state that most securely
Old Mac can handle more good Scotch
Than anyone we know, sir,
And he can kick up quite a splotch
When once he starts to go, sir.
The Colonel comes in Foghorn's wake,
A jaunty, cheerful figure;
A martial noise he seems to make
His style is quite *de rigueur.*
You'll see him later on, I ween.
Assisted by the Major,
Each is and each has ever been
An excellent old stager.
And now there bursts upon our view
A person most excited,
He looks at me and then at you
To see if we're invited.
He wears a harried worried air
As if the trump had sounded,
As if his woes he can not bear
He is so teased and hounded.
It is not hard to guess his name
A double-barreled label—
My muse has gone so cursèd lame
These lines resemble Babel.
'Twere quite unfair to many good
Substantial souls like Penhale
Who do their best, as heroes should,
When feeling ill or *when* hale,
To overlook their many claims
To be embalmed in verse.
Of Penhale be it briefly noted
He *seems* a sport, or worse,
Whereas, he's properly devoted
To abstinence and tea.
And Ferrier must not be missed,
A regular Ulysses, he
Is quite at home with tuff or schist.
A man of firm opinion,
Canadian to the core,
To none could he become a minion,
You could not ask for more.

. . . . .

I wander farther than I ought to
Much farther than at first was planned
Much farther than I ever thought to—
My subject's rather out of hand.
So I shall simply say adieu!
Here's "How" to every one of you!

GEORGE R. SMITH, Past-President,
and past-master in politics and prestidigitation.

E. T. CORKILL,
Inspector of Mines for Ontario. Strong on explosives. Has put the fear of God into more than one operator.



JAMES McEVOY,
Coal Protagonist of Pontonie—academic controversies on burro back over the Rockies a specialty.

DR. F. D. ADAMS, Past-President.

Star witness in famous breach of promise case at our Quebec Meeting, 1911.

JOHN E. HARDMAN.

Forest fires have destroyed the spinach. Not now so godly of visage. An after-dinner artist and a true blue sport.

EUGENE COSTE,

The stormy petrel of the Institute. Mr. Coste has enlivened proceedings more than a little.

THOS. CANTLEY, N. S. Steel & Coal Co.,
(these are synonyms).

MAJOR R. W. LEONARD.
Beloved of G.T.P. contractors.

A. A. COLE,
Mining Engineer T. & N. O. Railway. Dry nurse to many Cobalt excursionists.

DR. EUGENE HAANEL,
Director of the Mines Branch. Savant, specialist and administrator.

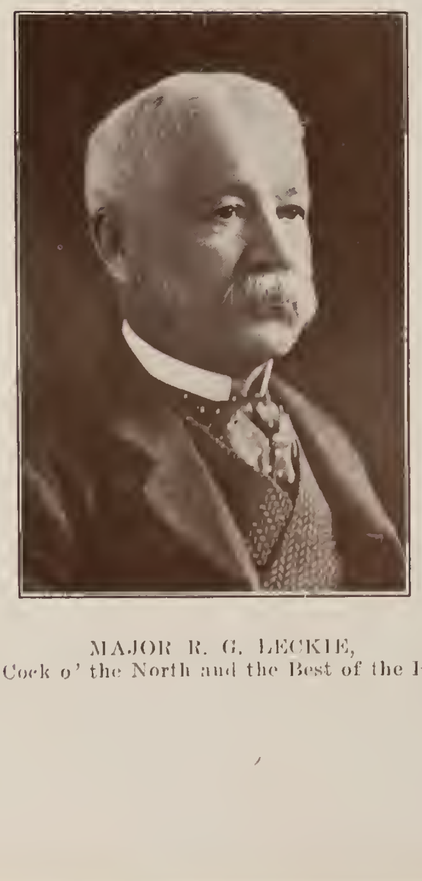
W. F. FERRIER.
Lately arrived from the States. A vehement Canadian. Discoverer of Canadian corundum.

H. MORTIMER LAMB, Secretary of the C. M. I.

G. G. S. LINDSEY,
An indefatigable official, organizer and entertainer.
Classified under the category of corker.

J. STEVENSON BROWN, Damon to Coste's Pythias.

DR. JAMES DOUGLAS, Scientist, Metallurgist and Author.



MAJOR R. G. LECKIE,
the Cock o' the North and the Best of the Bunch.

J. OBALSKI,
the former Superintendent of Mines for Quebec.

J. B. TYRRELL,
Explorer, geologist and author. Capable of unbending.

A. B. WILLMOTT.
Not now a partner of Julian Hawthorne.

J. C. GWILLIM,
Professor of Mining, Kingston.

R. W. BROCK, Director Geological Survey.
Much in need of a patriarchal beard. Otherwise beyond reproach.

DR. W. L. GOODWIN,
Director Kingston School of Mining. One of the Old Guard. Capable yet of staying up till after midnight.

COL. A. M. HAY,
without whom the Institute would cease to interest us.

# PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assaye. Those who have claims and who require the services of a lawyer, with a t' orough knowledge of Mining Law, should be very careful with whom they place their business.

# *Rigid Tests Insure The Reliability of —*

Baldwin-Westinghouse Mine Locomotive

# Baldwin-Westinghouse Mine Locomotives

WHEN you receive a Baldwin-Westinghouse Mine Locomotive, you have the full assurance that it will do your work properly, not only when new, but after years of continuous service.

Nothing has been left to chance. Your haulage has been carefully studied by engineers of wide experience, and your locomotive has been selected to operate satisfactorily under the worst conditions, with a large margin for unforeseen emergencies.

But assurance does not rest solely on experienced design. Each completed locomotive is thoroughly tested on a special rack, so that its exact performance can be obtained and compared with the service for which it is intended. The motors are also carefully tested before being placed in the locomotive.

When the locomotive is finally passed for shipment, its ability to give satisfactory service is a certainty.

*Full information on these Locomotives can be obtained by applying to nearest office.*

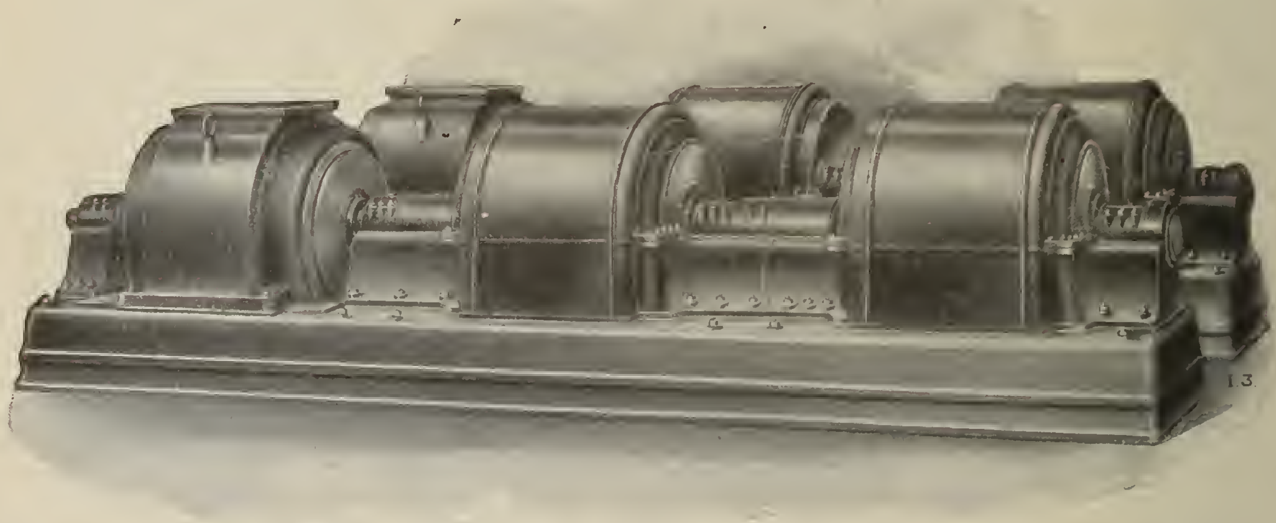
# TURBO-COMPRESSORS

DESIGNED AND BUILT FOR

## High - Speeds and Large Capacities

In various fields superior to the ordinary reciprocating Air Compressors for

## EFFICIENCY *and* RELIABILITY



TURBO-COMPRESSOR DRIVEN BY ELECTRIC MOTOR

Capacity 21,500 Cubic Feet Free Air per minute delivered against 120lbs. Gauge Pressure.
Built for Victoria Falls and Transvaal Power Company, Ltd., Johannesburg.

Recognizing the advantages of and the demand for Turbo-Blowers and Compressors over Reciprocating Air Compressors in various fields, the Worthington Company secured the exclusive rights for the products of Messrs. Pokorny & Wittekind, of Frankfort, A.-M., Germany. The differences between centrifugal pumps in the manufacture of which this company has been most successful, and turbo-blowers and compressors, are principally such as are required to adapt the compressors for handling light and elastic fluids, instead of the heavy and almost incompressible water.

The Turbo-Compressors are built in capacities of 5,000 cu. ft. of free air per min. and over, and speeds of 3,000 to 4,500 r.p.m. They require to be direct driven by either a steam turbine or a 60 cycle motor.

For further particulars and statement of advantages see Bulletin No. 201.

# This Lamp

is made with the precision of an Admiralty Gun. It is compact, strong and absolutely safe and is easily manipulated.

The lamp and apparatus is covered by over 50 Patents, which effectually stop competitors offering such high-class articles.

The article which even the best of our competitors are offering is such as we have discarded years ago as being unsafe.

We can supply a lock to be opened by compressed air and a self-contained underground re-lighting machine, worked by magneto, which saves the cost of igniter ribbons.

# FOUR GREAT MINING BOOKS

### Mining Without Timber

By
**Robert B. Brinsmade**
309 pp., illus., $3.00

This is the first book on those modern mining methods which require the minimum of timber.

Mr. Brinsmade has collected all the best material which has appeared to date. It covers the various methods of leading mines. It is full and complete on Open Cut, Stoping, Back Caving, Block Caving Slicing, etc.

### Timbering and Mining

By **W. H. Storms.** 300 pp., fully illustrated, $2.00 (8/6).

A practical treatise on American methods. Mr. Storms has written the matter in a clear, straightforward way, and kept in mind, always, the practical and economical features.

### Cost of Mining

By **James R. Finlay.** 415 pp., illustrated, $5.00 (21s).

The results of the leading mines of the world are presented in this book. It gives detailed analysis of the costs of mining coal, iron, lead, zinc, copper, gold and silver.

### Principles of Mining

By **H. G. Hoover.** 200 pp., illustrated $2.50 (10/6).

The standard treatise. The three parts are: First—The valuation. Second—The development of tunnels, shafts etc., with valuable material on equipment and efficiency. Third—The administration of mines, problems of labor, efficiency, costs, etc.

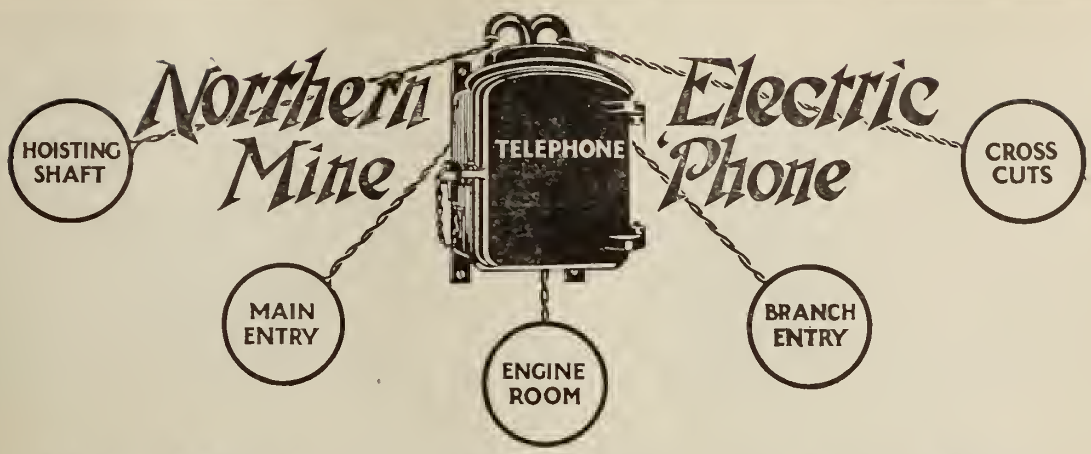
**We manufacture the most complete line of Diamond Drills of any concern in the world. 20 varieties, 350 to 6,000 feet, $400 to $10,000. Hydraulic Feed, Screw Feed, Hand Power, Horse Power, Gasoline, Steam, Air and Electricity. Send for Catalogue.**

## Standard Diamond Drill Co.

**745 First National Bank Building,**
**CHICAGO, U.S.A.**



## One Minute to Any Part of Your Mine

You can reach the farthest part of your workings and yet keep within instant touch of engine-room, hoist-shaft or your own office. The Northern-Electric Mine Telephone is one of the greatest time-savers ever produced for the mine manager and the labor he employs. It saves many a step and increases efficiency all around. Its value as an emergency call would alone warrant its installation in your mine ; but it will easily pay for itself in the time equivalent of many hundreds of dollars.

*A post card addressed to our nearest branch house will bring you full information. Send for it to-day.*

# MINING ENGINEERS' EXAMINATION AND REPORT BOOK

By CHARLES JANIN (*Consulting Mining Engineer*)

In Two Parts Part I, 94 Pages, 5½ x 7½ in. Leather; Part II, 57 Pages, 7½ x 5 in. Boards **$2.50 Postpaid**

PART I is a handbook covering examination of and reporting upon mines and mining property. Part II is a skeleton report, serving three purposes: *First*, an outline of a model report; *Second*, a field note book; or *Third*, a blank form on which the final report may be submitted.

The first pages of Part I are devoted to an enumeration of the points which a complete report should cover. These pages also constitute detailed instructions for filling out the blanks in Part II. The sub-headings are: Names of Claims, Location, Titles, History, Topography, Geology, Mining Facilities, Equipment. Development, Methods of Working, Production, Methods of Ore Treatment, Sampling, Ore Reserves, Operating Costs, Mine Valuation.

The examination of placers is fully discussed and an outline of a placer report is given. Methods and cost of Sampling with Keystone and Empire Hand Drills are included.

The following headings give the contents in brief of the remaining pages, each subject being treated in a short, concise, but accurate article: Examination of Title, Blank Forms, Classification of Igneous Rocks, Study of Ore Deposits, Representative Costs (including much actual cost data), Weights and Measures, Conversion Tables and Factors, Amount of Material Required for Buildings, Water Power (including the flow of water in flumes, ditches and pipes; horse power of water, etc.). Power Plants, Transmission Lines, Relative Values of Wood, Coal and Oil for Fuel, Company Reports, Flow Sheets, etc. Blank pages for individual notes are included.

Part II may be used to serve either of the three purposes noted above. It is printed upon a good bond paper which takes ink freely. On the pages intended for maps a background of cross section paper is printed in gray ink, making an ideal sketching medium. Part II fits snugly in a pocket at the back of Part I and the complete work will go easily into the ordinary coat pocket. Part II is sold separately at 50 cents each.

## THE FIFTEENTH ANNUAL MEETING OF THE CANADIAN MINING INSTITUTE

Much was expected of the Institute's fifteenth annual meeting. Expectations were not dissapointed. The Ottawa Branch appointed a vigorous Executive Committee. Aided by members of the Geological Survey and others, this committee did its duty nobly. In fact, there was hardly a dull moment during the three days of session. The hotel accommodation and service were hyper-excellent. The new Chateau Laurier is a thing of beauty. Ottawa at last possesses an hotel for which it need not blush. The outstanding features of the whole meeting, apart from certain papers to which reference will be made later, were the business sessions, the smoker and the dinner. At the business sessions there were discussed resolutions submitted by two prominent members, supported by several others and criticized by several. The resolutions were defeated; but their end is not yet. In essence they met the approval of the whole assembly. In form they were not acceptable. In view of subsequent development we can see no adequate reason for the postponement of an obviously necessary duty. Sooner or later the Institute will pass these or similar resolutions.

The resolutions in question were foreshadowed in an editorial in our issue of March 1st. Since they were intended to embody the opinion of the Institute, and did not take the form of a memorial to the Government; and since no more effective occasion could possibly have been chosen, it seems indeed superfluous to have permitted considerations of expediency to have overruled all else. A request for an entirely autonomous Domonion Department of Mines is reasonable. They express the Institute's need of more action—participation in legislation is neither undignified nor untactful. To impress the importance of the mining industry upon the country's representatives is neither untimely nor reprehensible. In fact, both the Premier and Sir Wilfrid Laurier gave evidence in their admirable speeches on Friday night of their general desire to do everything possible for the industry. We believe that both might have spoken more strongly had they had as a working basis a carefully worded resolution from the Institute. Hence it follows that a rare opportunity was missed. It remains for the Council to take the matter up as promptly as is feasible. In fact, a letter vote may prove a satisfactory remedy for the miscarriage at Ottawa.

The reading of Dominion and Provincial statistics brought out a most satisfactory state of affairs. The enormous growth of the mining industry during 1912 was amply demonstrated. His Royal Highness the Duke of Connaught, Governor-General of the Dominion of Canada, formally opened the proceedings in a felicitous and graceful speech. His Royal Highness, moreover, had the privilege of listening to a description of the Sudbury ore deposits by Dr. A. P. Coleman.

Dr. Coleman used none but a few necessary technical terms, and it would be hard to conceive of anything more lucid, instructive and interesting than his brief talk. Would to high Heaven all speeches were like his!

It is a matter of congratulation that the Institute can command such sterling papers as those presented by Dr. James Douglas, to whom, by the way, all the members should be grateful for his unceasing and active interest in the society. Of the great bulk of the papers read it may be asserted that they were well up to the average. Professor H. E. T. Haultain's address on "The Geologist" was a carefully prepared statement on a very delicate subject. Not only was it well received, but it excited more discussion than did any other. It was at once an appreciation of the geologist and calm, though searching, analysis of the relationship subsisting between him and the mining engineer. It was well and heartily received.

The brief announcement on the programme that, on Thursday evening, "a smoking concert will be held in the ball-room of the Chateau Laurier at 8 p.m.," was totally misleading. An enthusiastic audience was treated to a "Diastrophic Musical Tragedy," the alteration titles of which were, "The Mining World, or the Stinging Wildcat of Cobalt." Two of the leading characters in the tragedy were studied replications of two eminent Canadian geologists—one of whom has not been unconnected with Cobalt, the other not far distant from the presidential chair. Both were portrayed to admiration. The remaining characters were composite pictures of types ranging from the bemonocled English expert to the capable bartender. While the bar was the real motiff of the play, there was sufficient geology intermixed to serve the true and right purpose of confounding facts. Intelligent as was the audience, it is nevertheless a sad fact that many of the best points passed without applause. The apparently unrehearsed incidents of the play threw new light upon the characters of Messrs. Barlow, Denis and Obalski. These were the actual culmination of the tragedy. The audience was not infrequently moved to tears.

* * * *

As for the annual dinner it is difficult to speak in terms of too warm appreciation. The presence of the Premier, Sir Wilfrid Laurier and of other distinguished guests, lent diginity and meaning to the occasion. The speeches of both the first-named gentlemen and of Senator Pope were of prime importance to the future of the industry. The position of those who submitted the rejected resolutions was fully sustained.

To the Ottawa Branch the success of the meeting is in a large measure to be credited. They spared no pains. The President, Council and Secretary did all that in them lay to further that success. Special thanks, of course, are due to His Royal Highness, the Duke of Connaught, to the Rt. Hon. R. L. Borden, to Sir Wilfrid Laurier and to all the eminent gentlemen who honoured the convention with their presence. It is much to be regretted, however, that for the first time in years the Domonion Minister of Mines did not appear either at the ordinary sessions or at the dinner. Comment would be unfair, as we are ignorant of the reasons for the Hon. Mr. Coderre's apparent oversight. Yet it may be pointed out that the situation is open to several interpretations.

The praiseworthy attempt to arrange in groups the papers read was not as fruitful of good as we had hoped. Discussion lagged. The remedy for this is in the hands of the members. The President and the Secretary obviously did their best. However, this word of dispraise must not be taken too seriously. We may add that the papers themselves made amends for any defective arrangements. Possibly, and the matter can only be determined by trial, few papers might be presented.

* * * *

But in all essentials, in goodfellowship, in professional gain, in academic disquisition, and in social import, the fifteenth annual meeting of the Canadian Institute will go down into history as one of the most remarkable in the society's annals.

---

# CANADIAN MINING INSTITUTE ANNUAL MEETING 1913.

## DR. A. E. BARLOW'S PRESIDENTIAL ADDRESS.

Before commenting on the main theme upon which I propose to address you on this occasion, it is fitting that I should make some reference to the work of the Canadian Mining Institute during the past year. To occupy the office of President of an Association such as ours, is, indeed, a high honour, but it also represents a heavy responsibility. I have been particularly fortunate during my tenure of office in receiving the loyal and enthusiastic support of the members, and it is most gratifying to be in a position to state that the Institute to-day is in a better and more flourishing condition than at any time in its history. If in the past there have been from time to time factional differences, these have now disappeared and in their place we have harmony and good will. Occasionally, however, a complaint is heard emanating usually from younger members of the society, that the Council is not sufficiently liberal in its support of the local branches or sections. The majority of those present to-day will doubtless remember that the financial assistance to branches was a question thoroughly discussed at the annual meeting held in Montreal four years ago (1909). At that meeting it was definitely decided that it would be unwise to adopt a policy that would cripple the parent association, and might well lead to its bankruptcy. The present sound financial position of the Institute is due to the conservative policy that the Council has persistently followed. The enviable position which the Institute occupies is largely due, therefore, to the unselfish interest and willing devotion of its officers and individual members. As a matter of fact, the members whose admission to the Institute is recent, that is to say, within the last four or five years, get a great deal more by way of return for their annual subscriptions than did their seniors in point of membership. The Canadian Mining Institute at the present time gives in actual monetary equivalent at least as good a return to its members as does any similar society in the world, while in comparison with many this consideration is much greater. Only recently I had occasion to refer to some of the earlier volumes of the Journal embodying the transactions of the society, and any member who will do the same and will compare these earlier publications with the annual volumes now issuing, will be as agreeably impressed as I was with the extraordinary difference from every point of view. The first volume of the transactions published in 1898 contains 66 pages, inclusive of the papers, reports of the general meeting, annual meetings, constitution and by-laws, and list of members. The next three volumes never exceeded 350 pages and were similarly inclusive of all the activities of the society. Many of the papers then submitted and published would unquestionably be rejected by our present Publication Committee. Errors of statement as well as those of typography are noticably frequent. In short, these earlier volumes, both as regards subject matter and manner of treatment are far from comparable with the Journals of the proceedings of the last few years, comprising as they do, volumes of 700 pages and upward of well written, carefully edited and adequately printed theses of a very high average quality.

With further reference to Branches, it may be affirmed that the Council appreciates the benefit accruing to the Institute as a whole from their establishment, and, if conditions permitted, would gladly contribute to their support. But as this is not at present possible, it is necessary that the officers of the respective Branches should encourage among their members that same spirit of unselfishnes which has ever characterized the Institute. If such an attitude be maintained and strengthened, the sphere of influence of the Institute will indeed be extended.

As has been well said by a former President, the Canadian Mining Institute represents an industry, not a profession. With this fact before us, and remembering the necessarily more open membership qualifiiation, there is evidently necessary a much greater degree of that esprit de corps which contributes so largely to the success even of those exclusive professional associations. Apropos of the increase of membership it is gratifying to note that last year constituted a record, the accessions representing no less than 197. The total membership at the end of February (1913) was 1,052, classified as follows:

MEMBERSHIP.

| | Dec. 31, 1912. | Elected in 1913. | Resignations. | 1913. |
|---|---|---|---|---|
| Patrons | 5 | .. | .. | 5 |
| Honorary | 3 | .. | .. | 3 |
| Corresponding | 13 | 3 | .. | 18 |
| Ex-Officio | 31 | .. | .. | 31 |
| Members | 737 | 22 | 5 | 754 |
| Associates | 125 | 3 | 5 | 123 |
| Life | 8 | .. | .. | 8 |
| Students | 15 | .. | .. | 15 |
| Affiliated | 97 | .. | .. | 97 |
| | 1,034 | 28 | 10 | 1,052 |

To the Past-Presidents and Council of the Institute I desire to express my hearty appreciation and thanks for their earnest co-operation and unity of purpose, without which the present eminently satisfactory condition in the affairs of the Institute would have been impossible.

## THE NATIONAL IMPORTANCE OF MINING.

The subject of my Presidential adress, a subject of great interest, no doubt, to all members of the Canadian Mining Institute as well as to the general public, is "The National Importance of Mining." The title is by no means new or original, for under this same caption in 1902 one of our Past Presidents, Mr. John E. Hardman, presented a paper which, as he explained, he chose rather than the more specific title of "Government Aid to Mining," for the reason that he wished to emphasize the duty of the nation rather than the duty of the provinces to encourage an industry which has grown to be of such great importance to the Dominion. Mr. Hardman, assuming "that the national importance to which the industry of mining has attained, is axiomatic, proceeds to discuss how the Federal Government can best assist and promote such an industry, not only to greater dimensions, bu also to greater perfection, while still preserving and maintaining fidelity to that branch of the British North America Act by which the control and administration of minerals found within the borders of any particular province was vested in that province." This paper and the discussion following, which was shared by many mining men of prominence in Canada, afforded much necessary information and opinion on this even now timely subject. Our Secretary, Mr. H. Mortimer-Lamb, at this meeting, taking as his text, "State Aid to Mining in Australasia," will present some analogies and conclusions as to governmental assistance to the mining industry.

In this address, however, I do not propose to consider this aspect of the question, but simply to present in facts and inferences regarding the growth and relative importance of mining in Canada, especially in comparison with other industries that depend directly on the exploration and utilization of our natural resources. Minerals, in the widest acceptation of the term, are the basis of the business of mining. They are used either directly or indirectly in every branch of industry, so that it may fairly be said that the measure of a nation's civilization and progress is directly proportionate to the development of its mineral resources, especially those of coal and iron. Cities, towns and even villages, often have their location determined by the presence of some mineral of economic importance; while others, again, owe much of their importance to such proximity. The great centres of industrial activity are directly dependent for their growth on an adequate supply of the raw minerals or mineral products. The might and power of England, as well as the extension of the Empire of Greater Britain to all parts of the habitable globe, are primarily traceable to the occurrence within this tight little island of mineral resources that are unique for their abundance and variety. The rise to eminence and wealth of the United States of America has accompanied the development and utilization of the mineral resources. In addition, each individual State included in the republic owes much of its importance to the possession of minerals whose exploitation has added to the comfort and wealth of its inhabitants. Thus, Alabama has coal and iron; California, gold, quicksilver and petroleum; Indiana, natural gas, building stone and coal; Maine, granite; Michigan, copper and iron; Minnesota, iron; Missouri, lead, zinc and iron; New Jersey, zinc, marble and clays; Ohio, coal, building stone, natural gas and petroleum; Pennsylvania; coal, iron and petroleum; and Tennessee and Vermont, marble.

There are four principal industries based upon the development and utilization of our natural reesources. In the value of their production, agriculture is preeminently first in rank, representing in 1911 a total of $565,711,600. The mineral industry is easily second, with a production in 1910 valued at $106,823,623. In 1910, it was nearly equal in value to the production from the fisheries and forests combined. The value of these two latter in 1910 was $113,954,433. (Forestry $83,989,000; fisheries, $29,965,433).

The relation of the mineral industry to the existing railways also brings out forcibly the importance of mining. This connection is ably illustrated in a paper submitted by Dr. James Douglas to the Institution of Mining and Metallurgy at its nineteen session (1909-1910) entitled "The Influence of the Railroads of the United States and Canada on the Mineral Industry." (Vol. XIX, pp. 2-56). One of the tables quoted shows that the freight supplied to the railways by the mines is far in excess of that contributed by any other branch of national activity. Thus in the United States in 1900, the products of the mine, according to the Interstate Commerce Commission, contributed 52.59 per cent. of the total freight carried by the railways, manufacturers ranking second with 13.41 per cent. In 1906 the products of the mines had increased to 53.09 per cent. of the total freight carried, while manufacturers were again second with 14.81 per cent. In Canada, in 1908, of the total freight hauled by the various railroads in operation, the products of the mines accounted for 35.92 per cent. of the total, while forestry products ranked second in importance, with 20.49 per cent., and agriculture third, with 14.91 per cent.

In order to obtain a true perspective of the national importance of mining to Canada, a brief historical outline seems necessary:

The first recorded mining excitement relating to Canada, was that occasioned by the discovery of some mica reported to contain a considerable proportion of gold, brought back to England by Sir Martin Frobisher in 1576. The great expectations aroused by this find inspired a second and even a third voyage, and the captain was specially directed by commission to search for this gold ore rather than for the discovery of the (Northwest) passage. On the second voyage, in 1577, it is related that they took 200 tons of glittering ore on the southern side of Frobisher's Strait, "but upon tryall made, it proved no better than blacklead and verified the proverb—All is not gold that glistereth." The third voyage, undertaken in 1578, for the purpose of founding a colony and collecting ores, was barren of results.

The limonite or bog iron ore deposits, in the district of Three Rivers, were described as far back as the latter part of the seventeenth century, and in 1737 a blast furnace was erected and smelting operations undertaken which have been carried on more or less continuously to the present time. The existence of workable deposits of copper in the vicinity of the Great Lakes, had long been known, but in 1767 a trader named Henry who had passed the winter at Michipicoten, reported the existence of lead at Maminse and of grey copper ore at that and various other places. In 1770, a company was formed in England, but the narrowing of the vein to 4 inches at a depth of thirty feet, the difficulty of procuring and maintaining mines at so great a distance from any centre of civilization, the remoteness of any market for the ore, as well as the absence of facilities for transportation, rendered these first attempts abortive.

The first mention of the occurrence of coal in Canada, as also in America, is contained in a small book published in Paris in 1672; but mining was not undertaken until 1720, when an opening was made on the north side of Cow Bay, from which coal was obtained for the men working on the fortifications of Louisburg. During the next sixty years the mining of coal was carried on in a desultory fashion, but from 1784 to 1788 the Government itself carried on systematic mining operation on the northwest shore of Sydney Harbour. From 1788 to 1826 these mines were either leased to individuals or worked by the Government, the output varying from 200 to 1,200 tons per year. In 1826 and 1827 the General Mining Association acquired all the ungranted mines and minerals of Cape Breton, and in 1830 the first shaft in the province was sunk on the main seam on the west side of Sydney Harbour.

Douglas, the celebrated botanist, discovered the Blue Bell (silver-lead) mine on Kootenay Lake, British Columbia, in the early twenties. Coal was discovered at Fort Rupert, Vancouver Island, in 1835, and some development work was done by the Hudson Bay Company; but these workings were abandoned in 1851 for those at Nanaimo, where coal mining has ever since been carried on. In 1850 gold was found on Vancouver and Queen Charlotte Islands, and a miniature mining boom took place at the Queen Charlotte Islands in 1851-52. In the interior of British Columbia, gold was found in the Natchey Pass and the Similkameen as early as 1852. In 1852 and 1854, Colville Indians were known to have gold nuggets in their possession, and Chief Trader McLean procured gold dust from Indians near Kamloops in 1852. Between 1855 to 1857 gold discoveries were made on the Thomson, Fraser and Columbia Rivers, and the news soon attracted attention to British Columbia as a possible gold field and first opened it up for settlement.

(To be continued.)

# PRELIMINARY REPORT OF THE MINERAL PRODUCTION OF CANADA, 1912†

Statistics subject to revision.

The total value of the mineral production in Canada in 1912 was $133,127,489 according to the preliminary statistics published herewith, which are based upon direct returns from mine and smelter operators, but subject to final revision. Compared with the previous year this production shows an increase of $29,906,495, or nearly 29 per cent. The mineral output in 1911, however, was somewhat restricted owing to long extended labour disputes and the largest previous production was in 1910 compared with which that of 1912 shows an increase of $26,243,866, or over 24 per cent. The per capita production in 1910 was $14.93, and this has increased in 1912 to over $18. This record is a gratifying indication or confirmation of the fact that the Canadian mineral industry in 1912 has had by far the most successful year in its history.

This progress is all the more satisfactory because it is evidently due to a widespread and substantial development of the country's mineral resources. The only new camp of importance to contribute largely to the year's output was Porcupine, the gold production of which was about one and three-quarter million dollars. A slight scarcity of labour was reported, particularly in connection with the asbestos and clay working industries. There were compartively few clay bour disputes to interfere with output, the principal difficulties being a strike of coal miners on Vancouver Island, beginning in September, and a labour dispute at Porcupine toward the latter part of the year. The total coal and gold production were but slightly affected thereby.

A substantial increase in price in most of the metals, which took place early in the year and continued throughout, had a very important bearing on the year's operations and contributed largely to the increased value of the output.

A feature of particular interest during the year has been the continued and extended development of ore reserves. The satisfactory results from these operations particularly in the case of the nickel-copper ores of the Sudbury district, the Porcupine gold ores of Ontario and a number of the copper and lead deposits of British Columbia, point to much greater annual outputs in the future.

Extension of ore smelting and refining facilities and in a number of cases special improvements in methods of practice have also been important factors in the year's operations.

The production of the more important metals and minerals is shown in the following tabulated statement in which the figures are given for the two years, 1911 and 1912, in comparative form, and the increase or decrease in value shown. Tabulated statements in greater detail, will be found on subsequent pages of this pamphlet:

| | 1911. | | 1912. | | | Increase (+) or decrease (—) in |
|---|---|---|---|---|---|---|
| | Quantity. | Value. | Quantity. | Value. | | value. |

†Presented by Mr. John McLeish at Ottawa Meeting.
*Short tons throughout.

The subdivision of the mineral production in 1911 and 1912 by provinces was approximately as follows:

| Province. | 1911. Value of production | 1911. Per cent. of total. | 1912. Value of production. | 1912. Per cent. of total. |
|---|---|---|---|---|
| Nova Scotia | $15,409,397 | 14.93 | $18,843,324 | 14.15 |
| New Brunswick | 612,830 | 0.59 | 806,584 | 0.61 |
| Quebec | 9,304,717 | 9.01 | 11,675,682 | 8.77 |
| Ontario | 42,796,162 | 41.46 | 51,023,134 | 38.33 |
| Manitoba | 1,791,772 | 7.74 | 2,314,922 | 1.74 |
| Saskatchewan | 636,706 | 0.62 | 909,934 | 0.68 |
| Alberta | 6,662,673 | 6.46 | 12,110,960 | 9.10 |
| British Columbia | 21,299,305 | 20.63 | 29,555,323 | 22.20 |
| Northwest Territories | 4,707,432 | 4.56 | 5,887,626 | 4.42 |
| Dominion | $103,220,994 | 100.00 | $133,127,489 | 100.00 |

Of the total production in 1912 a value of $61,177,989 or nearly 46 per cent. is credited to the metals, and $71,949,500 or 54 per cent. to non-metallic products. With the exception of petroleum every important mineral mined in Canada shows an increased production in 1912, in so far as value is concerned. In the case of silver only, is there a decrease in quantity, and this slightly less than 2 per cent., the increase in total value of silver being due to the much higher price obtained for the metal during the year. Among the metals, increases in quantity of output are shown as follows: pig iron, 10.5 per cent.; gold, 10.5 per cent.; gold, 28 per cent.; copper, 40 per cent., and lead, 50 per cent. On account of the generally higher prices of the metals the increases in total value of output considerably exceed the increases in quantity, and are as follows: silver 12 per cent., nickel 31 per cent., copper 85 per cent., and lead 93 per cent.

The most important increases among non-metallic products are in coal, gypsum and cement. Coal shows an increase of 30 per cent. in tonage, gypsum 11 per cent. and cement 26 per cent.

It is a matter of regret to have to report a continued decrease in the production of petroleum. The Canadian output of this product a few years ago was about 50 per cent. of domestic consumption. At the present time not over 5 per cent. of Canada's consumption of petroleum and its products is derived from domestic sources.

The record of production by provinces given above, shows some slight changes in the relative importance of the production of each. The only change in the order of magnitude of output is that Alberta, the production of which had exceeded that of Quebec in 1910, but fallen below again in 1911, on account of its restricted coal output, again takes premier place in 1912. Ontario is still the largest contributor to the total, being credited with 38 per cent., or $51,023,134; British Columbia comes second with 22 per cent., or $29,555,323; Nova Scotia third with $18,843,324, or 14 per cent.; Alberta fourth with $12,110,960, or over 9 per cent., and Quebec fifth with $11,675,682, or a little under 9 per cent.

It should be remembered in dealing with these comparisons that Nova Scotia in the above record is given no credit on account of the large iron smelting and steel making industries at Sydney, New Glasgow, etc. The pig iron made here is entirely from imported ore and naturally is not credited as a Canadian mine output. The same remark applies to a large percentage of the pig iron production in Ontario as well as to the production of aluminium in Quebec.

There was an increased output in each of the provinces in 1912, the largest gains being in Alberta and British Columbia.

In Nova Scotia both coal and gypsum mining were particularly active though a reduced production of gold is reported. Copper and asbestos mining in Quebec contribute chiefly to the increase in that province.

Ontario had important increases in nickel and copper but more especially in gold from the Porcupine district. This province has a large output of non-metallic products including cement, clays, etc. In Alberta coal mining has had a record year exceeding in tonnage the British Columbia production. In the latter province the principal increase was in copper, with gold, silver, lead, zinc, coal and structural or building materials as important contributors.

## Smelter Production.

General statistics showing the quantities of ores treated at smelters and the quantities of refined metals or smelter products obtained have been collected by this branch since 1908. It should be explained that the accompanying statistics include the treatment of a small quantity of imported ores chiefly in the British Columbia smelters.

The total quantity of ores, concentrates, etc., treated in 1912, was 3,008,559 tons as compared with 2,193,553 tons in 1911.

The ores treated may be conveniently classified as follows:

*Quotations furnished by Messrs. Thomas Robertson & Company, Montreal, Que.

| | 1910. Tons. | 1911. Tons. | 1912. Tons. |
|---|---|---|---|
| Nickel copper ores | 628,947 | 610,834 | 725,065 |
| Silver-cobalt nickel-arsenic ores | 9,466 | 9,330 | 8,136 |
| Lead and other ores treated in lead furnaces | 57,549 | 55,408 | 63,042 |
| Copper-gold-silver ores | 1,987,752 | 1,517,981 | 2,212,316 |
| Total | 2,683,714 | 2,193,553 | 3,008,559 |

The products obtained in Canada from the treatment of these ores include: refined lead produced at Trail, B.C., and fine gold, fine silver, copper sulphate, and antimony produced from the residues of the lead refinery; silver bullion, white arsenic, nickel oxide, and cobalt oxide produced in Ontario, from the Cobalt District ores. In addition to these refined products, blister copper, copper matte, nickel-copper matte, cobalt material or mixed nickel and cobalt oxides are produced and exported for refining outside of Canada.

The aggregate results of smelting and refining operations may be summarized as shown in the next table. Unfortunately the figures cannot be taken to represent the total production from smelting ores mined in Canada, since considerable quantities of copper and silver ores are still shipped to other smelters outside of Canada for smelting.

| | 1911. Refined products. | 1911. Metals contained in matte blister, base bullion and speiss. | 1912. Refined products. | 1912. Metals contained in matte blister, base bullion and speiss. |
|---|---|---|---|---|
| Gold, ozs. | 15,270 | 175,189 | 12,118 | 184,815 |
| Silver, ozs. | 19,078,768 | 585,896 | 17,877,914 | 686,171 |
| Lead, lbs. | 23,525,050 | ...... | 35,893,190 | ...... |
| Copper, lbs. | ...... | 29,855,868 | ...... | 58,405,910 |
| Copper sulphate | 197,187 | ...... | 87,110 | ...... |
| Nickel | ...... | 34,098,744 | ...... | 44,841,542 |
| *Nickel and cobalt oxides | 1,415,006 | ...... | 1,634,087 | ...... |
| White arsenic | 4,194,209 | ...... | 4,090,756 | ...... |

Smelter products shipped outside of Canada for refining were: blister copper carrying gold and silver values 17,069 tons in 1912, as compared with 10,710 tons in 1911; copper matte carrying gold and silver values 6,727 tons in 1912, as against 11,320 tons in 1911; Bessemer nickel-copper matte carrying small gold and silver value as well as metals of the platinum group 41,925 tons in 1912, as compared with 32,607 tons in 1911.

## Gold.

The gold production of 1912 is estimated at approximately $12,559,443, which compared with the 1911 production $9,871,077 shows an increase of $2,778,366.

The Yukon placer production in 1912 is estimated at $5,540,000, as against $4,580,000 in 1911, the total exports on which royalty was paid during the calendar year, according to the records of the Department of Interior, being 335,015.67 ounces in 1912 and 277,430.97 ounces in 1911. The British Columbia production in 1912 was $5,167,390, of which the placer production, as estimated by the Provincial Mineralogist, was $500,000, smelter recoveries and bullion obtained from milling ores being valued at $4,667,390. The main feature of the year was the large increase from Ontario due to the commencement of operations by several mills in the Porcupine district, the province producing $1,745,292 as against $42,625 in 1911.

In Quebec there is a small amount credited to the pyritic ores as well as a small recovery from Beauce county an dthe Nova Scotia estimate shows a further decrease.

The exports of gold-bearing dust, nuggets, gold in ore, etc., in 1912, were valued at $10,014,654.

Gold in bars, blocks, ingots, etc., was imported in 1912 to the value of $1,096,546.

## Silver.

In quantity there was a slight decrease in the silver production in 1912, returns to date showing a production of 31,931,710 fine ounces, an apparent falling off of 627,334 ounces, but due to the increased price, the value shows an increase from $17,355,272 in 1911 to $19,425,656 in 1912 or $2,079,384.

Of the 1912 production 29,190,122 ounces were from Ontario, 2,651,118 from British Columbia, the increases being from British Columbia and the Yukon.

For British Columbia the figures represent the recovery as millbullion or silver contained in smelter products, while for Ontario the figures represent the total silver content of ore and concentrates shipped, less five per cent. allowed for smelter losses, together with bullion shipments.

The total shipments of ore and concentrates from the Cobalt district and adjacent mines were about 29,116 tons, containing approximately 25,684,082 ounces, in addition to which 4,773,878 ounces were shipped as bullion.

There was also a small silver recovery from the gold ores of Ontario.

In Quebec the silver was derived from the pyritic ores of the eastern townships.

The exports of silver in ore, etc., as reported by the Customs Department were 34,911,922 ounces, valued at $19,494,416. There was also an importation of silver in bars, blocks, sheets, etc., valued at $822,020.

*Nickel oxide, cobalt oxide and cobalt material, etc., not all completely refined.

The price of silver in New York varied between a minimum of 54¾ cents per ounce in January and a maximum of 64⅛ cents in October, the average monthly price being 60.835 cents, compared with an average of 53.304 cents in 1911.

### Copper.

There is practically no recovery of refined copper in Canada and the production is represented by the copper contents of smelter of smelter products, matte, blister-copper, etc., together with the amount of copper contained in ores exported, estimated as recoverable.

The total production on this basis in 1912 was 77,775,600 pounds, valued at $12,709,311, as compared with 55,648,011 pounds valued at $6,886,998 in 1911, an increase in quantity of 22,127,589 pounds and in value of $5,822,313.

Quebec province is credited with a production of 3,225,523 pounds as against 2,436,190 pounds in 1911, the increase being due to the increased production from the pyritic ores of the Eastern Townships. Ontario's production in 1912 was 22,250,601 pounds, as compared with 17,932,263 pounds in 1911, being mainly derived from the nickel-copper ores of the Sudbury district.

Apart from the copper shipments from Dane, the most interesting occurrence was the payment made for copper in shipments from the Cobalt camp.

British Columbia had a record output of 50,526,816 pounds, having had a year of uninterrupted smelter operation free from strikes and other disturbances.

From the Yukon the Pueblo mine was a heavy shipper.

The New York price of electrolytic copper varied during the year between 13.75 cents per pound in February, to 17.60 in August, the average for the year being 16.341 cents, as against an averaeg monthly price of 12.376 cents in 1911.

The exports of copper in 1912 were: copper, fine in ore, etc., 76,542,643 pounds, valued at $8,800,276, and copper black or coarse and in pigs, 1,945,921 ponnds, valued at $236,212.

The total imports of copper in 1912 were valued at $7,052,534.

### Lead.

The total production of lead in 1912 was 35,763,476 pounds, valued at $1,597,554, or an average of 4.467 cents per pound, the average wholesale or producers price of pig lead in oMntreal for the year. In 1911 the production was 23,784,969 pounds, valued at $827,717.

The shipments were practically all from British Columbia mines in 1912, a small shipment being made from Ontario mines, but not paid for. Towards the close of the year the North American smelter at Kingston, Ontario, started operations.

In British Columbia the resumption of active operations at the Blue Bell and the activity of the Consolidated Mining and Smelting Company and a number of the more imprtant purely mining companies have been factors in the increase.

The exports of lead in ore, etc., in 1912 are reported as 299,240 pounds, valued at $8,193. No pig lead was exported.

The total value of the imports of lead and lead products in 1912 was $1,806,221, including pig lead, bars, sheets, tea lead, etc., valued at $1,202,001; manufactures of lea dvalued at $200,157; litharge and lead pigments, valued at $404,063.

The total value of the imports of lead and lead products in 1911 was $1,049,276, being pig lead, etc., $706,020; manufactures, $108,012, and litharge and lead pigments, $235,244.

The average monthly price of lead in Montreal during 1912 was 4.467 cents per pound. This is the producers price for lead in car lots as per quotations kindly furnished by Messrs. Thos. Robertson & Co.

The average monthly price of lead in New York during the year was 4.471 cents, and in London £18.929 per long ton, equivalent to 3.895 cents per pound.

The amount of bounty paid during the twelve months ending December 31, 1912, on account of lead production, was $118,425.74, as compared with $219,557.70 in 1911.

### Nickel.

The mining and smelting of nickel-copper ores in the Sudbury District of Ontario, was carried on with greatly increased output during 1912. The same companies were in operation as in previous years, viz.: The Mond Nickel Company and the Canadian Copper Company operating mines and smelters, and the Dominion Nickel Company, developing and proving ore bodies. It is interesting to note that small shipments of nickel ore were also made from the Alexo Mine at Kelso, in the Nipissing district. This ore was smelted at Victoria Mines.

Considerable changes have been made in some of the details of smelting practice, although the general method remains the same, i.e., the ore is roasted, smelted and converted to a Bessemer matte containing from 77 to 82 per cent. of combined metals, copper and nickel, the matte being shipped to the United States and Great Britain for refining. A portion of the matte made by the Canadian Copper Company is used for the direct production of monel metal, an alloy of nickel and copper, without the intermediate refining of either metal.

The total production of matte in 1912 was 41,925 tons, valued by the producers, at the smelters at $6,303,102, an increase of 9,318 tons, or nearly 20 per cent. over the production of 1911. The metallic contents were copper 22,231,725 pounds, and nickel 44,841,542 pounds. The amount of ore smelted was 725,065 tons, which included 1,720 tons from the Alexo mine mentioned above.

The aggregate results of the operations on the nickel ores during the past four years were as follows in tons of 2,000 pounds:

| | 1909. Tons. | 1910. Tons. | 1911. Tons. | 1912. Tons. |
|---|---|---|---|---|
| Ore mined | 451,892 | 652,392 | 612,511 | 737,584 |
| Ore smelted | 462,336 | 628,947 | 610,834 | 725,065 |
| Bessemer matte produced | 25,845 | 35,033 | 32,607 | 41,925 |
| Copper content of matte | 7,873 | 9,630 | 8,966 | 11,116 |
| Nickel content of matte | 13,141 | 18,636 | 17,049 | 22,421 |
| Spot value of matte | $3,913,017 | $5,380,064 | $4,945,592 | $6,303,102 |

| | Lbs. | Lbs. | Lbs. | Lbs. |
|---|---|---|---|---|
| Nickel contained in matte, etc.: | | | | |
| Exported to Great Britain | 3,843,763 | 5,335,331 | 5,023,393 | 5,072,867 |
| Exported to United States | 21,772,635 | 30,679,451 | 27,596,578 | 39,148,993 |
| | 25,616,398 | 36,014,782 | 32,619,971 | 44,221,860 |

The price of refined nickel in New York remained practically constant throughout the year, quotations in the Engineering and Mining Journal being for large lots, contract business, 40 to 45 cents per pound except during the early part of May, when 40 to 50 cents was quoted. Retail spot from 50 cents for 500 pound lots up to 55 cents for 200 pound lots. The price for electrolytic is 5 cents higher.

## Iron.

**Iron Ore.**—Complete returns of iron ore production have not yet been received but shipments from Canadian mines in 1912 were probably about 175,000 tons.

The total shipments of iron ore from mines in 1911 were 210,344 short tons, valued at $522,319, and included 137,399 tons classed as rhematite and 72,945 tons as magnetite.

Exports of iron ore from Canada during 1912 were recorded by the Customs Department as 118,129 tons, valued at $382,005. The exports were chiefly from Bathurst, New Brunswick, and Torbrook, Nova Scotia.

Shipments from the Wabana Mines, Newfoundland, in 1912, by the two Canadian companies operating there, were 1,331,912 short tons, of which 956,459 tons were shipped to Sydney and 375,453 tons to the United States and Europe.

**Pig Iron.**—The total production of pig iron in Canadian blast furnaces in 1912 was 1,014,587 tons of 2,000 pounds, valued at approximately $14,550,999, as compared with 917,535 tons, valued at $12,307,125 in 1911.

Of the total output in 1912, 21,701 tons were made with charcoal as fuel and 92,886 tons with coke. The classification of the production according to the purpose for which it was intended was as follows: Bessemer, 256,191 tons; basic, 544,534 tons; foundry and miscellaneous, 213,862 tons.

The amount of Canadian ore used during 1912 was 71,588 tons; imported ore 2,019,165 tons; mill cinder, etc., 36,901 tons. The amount of coke used during the year was 1,265,998 tons, comprising 609,183 tons from Canadian coal and 658,815 tons imported coke or coke made from imported coal. There were also used 1,886,748 bushels of charcoal. Limestone flux was used to the extent of 705,613 tons.

In connection with blast furnace operations there were employed 1,358 men and $993,941 were paid in wages.

The production of pig iron by provinces in 1911 and 1912 was as follows:

| | 1911. | | | 1912. | | |
|---|---|---|---|---|---|---|
| | Tons. | Value. | Value. per ton. | Tons. | Value. | Value. per ton. |
| Nova Scotia | 390,242 | $4,682,904 | $12.00 | 424,994 | $6,374,910 | $15.00 |
| Quebec | 658 | 17,282 | 26.24 | ...... | ...... | ...... |
| Ontario | 526,635 | 7,606,939 | 14.44 | 589,593 | 8,176,089 | 13.87 |
| | 917,535 | $12,307,125 | 13.41 | $1,014,587 | $14,550,999 | 14.34 |

*The Nova Scotia producers do not place a selling value upon their pig iron production and the increased value used for Nova Scotia pig iron in 1912 does not mean that there has been an increase in the value as shown but that the value used in 1911 was probably too low.

There was also a production during 1912 in electric furnaces of 7,834 tons of ferro-alloys valued at $465,225, as compared with 7,507 tons valued at $376,404 in 1911.

The exports of pig iron during the year are reported as 6,976 tons, valued at $310,702, an average of $44.53 per ton. Probably the greater part of this is ferro-silicon and ferro-phosphorus produced respectively at Welland and Buckingham.

There were imported during the year 272,680 tons of pig iron, valued at $3,512,969, and 19,810 tons of ferro-manganese, etc., valued at $469,884.

## Asbestos.

The total shipments of asbestos in 1912 exceeded those of 1911 by at least 5 per cent., it being probable that complete returns will show a somewhat higher production and shipments than the figures given below. According to returns so far received, the total output of asbestos was 97,816 tons, the sales 106,520 tons, valued at $2,959,677, or an average of $27.79 and stock on hand at the end of the year amounting to 21,686 tons, valued at $1,021,066. The record indicates an increase in sales and a reduction of stocks on hand.

Shipments were confined to the mines of the Black Lake and Thetford districts, those at East Broughton remaining idle. Operators report that they were handicapped by shortage of labour, but since market prices and conditions have greatly improved, 1913 promises to be a very successful year.

The number of men employed in mines and mills during 1912, was 2,755, at a wage cost of $1,296,655.

The total quantity of asbestos rock sent to mills is reported as 1,514,314 tons, which, with a mill production of 97,815 tons, shows an average estimated recovery of about 6.45 per cent.

The following tabulated statement shows the output and sales during 1912, and the stock on hand at the end of the year.

| | Output. Tons. | Tons. | Sales. Value. | Per ton. | Stock on hand Dec. 31. Tons. | Value. | Per ton. |
|---|---|---|---|---|---|---|---|
| Crude No. 1 | 1,447¾ | 1,928.9 | $507,904 | $263.31 | 864.8 | $220.789 | $255.31 |
| Crude No. 2 | 3,224 | 3,669 | 372,357 | 101.49 | 2,719 | 293,263 | 107.86 |
| Mill stock No. 1 | 19,672 | 18,758 | 843,559 | 44.97 | 7,490 | 338,069 | 45.13 |
| Mill stock No. 2 | 35,389 | 43,359 | 855,902 | 19.74 | 6,278 | 132,349 | 21.08 |
| Mill stock No. 3 | 38,083 | 38,805 | 379,955 | 9.79 | 4,334 | 36,596 | 8.44 |
| Total asbestos | 97,815¾ | 106,519.9 | $2,959,677 | $27.79 | 21,685.8 | $1,021,066 | $47.08 |
| Asbestic | ...... | 24,740 | 19,707 | 0.80 | ...... | ........ | ...... |

In the absence of a uniform classification of asbestos of different grades the above subdivisions have been adopted purely on a valuation basis; crude No. 1 comprising material valued at $200 and upwards, and crude No. 2 under $200; mill stock No. 1 includes stock valued at from $30 to $100; No. 2 from $15 to $30; No. 3 under $15.

Output, sales and stocks in 1911 were as follows:

| | Output. Tons. | Tons. | Sales. Value. | Per ton. | Stock on hand Dec. 31. Tons. | Value. | Per ton. |
|---|---|---|---|---|---|---|---|
| Crude No. 1 | 1,467.9 | 1,301.4 | $342,855 | $263.45 | 1,256 | $327,508 | $260.75 |
| Crude No. 2 | 3,594.5 | 3,562.7 | 402,107 | 112.87 | 3,222.7 | 404,198 | 125.42 |
| Mill stock No. 1 | 20,379 | 18,315 | 916,678 | 50.05 | 8,471 | 380,570 | 44.93 |
| Mill stock No. 2 | 39,289 | 47,826 | 991,370 | 20.73 | 17,794 | 365,458 | 20.54 |
| Mill stock No. 3 | 31,572 | 30,388 | 269,052 | 8.85 | 3,823 | 31,367 | 8.20 |
| Total asbestos | 96,302.4 | 101,393.1 | $2,922,062 | 28.82 | 34,566.7 | $1,509,101 | $43.66 |
| Asbestic | ...... | 26,021 | 21,046 | 0.81 | | | |

Exports of asbestos during the twelve months ending December 31, 1912, are reported as 88,008 tons, valued at $2,349,353, as against 75,120 tons, valued at $2,067,259 exported in 1911.

### Coal and Coke.

With the exception of a partial interruption of work, on Vancouver Island during the last three months of the year due to a dispute of coal miners, coal mining was actively prosecuted in all important coal mining districts during 1912. Thus in contrast with 1911 when the output was seriously reduced by a long continued strike in Southern Alberta and British Columbia the production in 1912 shows a very large increase.

The total production of coal during the past year comprising sales and shipments, colliery consumption, and coal used in making coke, etc., was 14,699,953 short tons, valued at $36,349,299, as against 11,323,388 tons, valued at $26,467,646 in 1911, and 12,909,152 tons valued at $30,909,779 in 1910. The 1912 production exceeded all former outputs. Nova Scotia shows an increase of nearly 8 per cent., British Columbia an increase of over 26 per cent., though not quite up to the 1910 production. Alberta an increase of about 128 per cent. over 1911, and 19 per cent. over 1910. The other provinces show comparatively little change. The figures for the Yukon represent the production from the Tantalus field, no record having been received of the output below Dawson.

The production by provinces during the past three years is given below:

| Province. | 1910. Tons. | Value. | 1911. Tons. | Value. | 1912. Tons. | Value. |
|---|---|---|---|---|---|---|
| Nova Scotia | 6,431,142 | $12,919,705 | 7,004,420 | $14,071,379 | 7,791,440 | $17,391,608 |
| British Columbia | 3,330,745 | 10,408,580 | 2,542,532 | 7,945,413 | 3,220,899 | 10,065,311 |
| Alberta | 2,894,469 | 7,065,736 | 1,511,036 | 3,979,264 | *3,446,349 | 8,471,126 |
| Saskatchewan | 181,156 | 293,923 | 206,779 | 347,248 | 196,325 | 327,054 |
| New Brunswick | 55,455 | 110,910 | 55,781 | 111,562 | 42,780 | 85,560 |
| Qukon Territory | 16,185 | 110,925 | 2,840 | 12,780 | 2,160 | 8,640 |
| Total | 12,909,152 | $30,909,779 | 11,323,388 | $26,467,646 | 14,699,953 | $36,349,299 |

The exports of coal in 1912 were 2,127,133 tons, valued at $5,821,593, as compared with exports of 1,500,639 tons, valued at $4,357,074 in 1911, an increase in exports of 626,494 tons.

Imports of coal during the year included bituminous, round and run of mine 8,491,840 tons, valued at $16,846,727; bituminous slack 1,919,953 tons, valued at $2,550,922, and anthracite 4,184,017 tons, valued at $20,080,388, or a total of 14,595,810 tons, valued at $39,478,037.

The imports in 1911 were bituminous, run of mine, 8,905,815 tons; bituminous slack 1,632,500 tons, and anthracite 4,184,017 tons, valued at $20,080,388, or a total of 14,595,810 tons, valued at $39,478,037.

*Statistics furnished by Mr. John Stirling, Inspector of Mines, Alberta.

The imports in 1911 were bituminous, run of mine, 8,905,815 tons; bituminous slack 1,632,500 tons, and anthracite 4,020,577 tons, or a total of 14,558,892 tons.

The apparent consumption of coal in 1912 was thus 27,168,630 tons, as against an apparent consumption in 1911 of 24,381,641 tons.

**Coke.**—The total production of oven coke in 1912 was 1,411,219 tons, valued at $5,352,520, as compared with a production of 935,651 tons, valued at $3,630,410 in 1911. A considerable percentage of this is made from imported coal.

By provinces the production in 1912 was: Nova Scotia 625,908 tons, Ontario 379,854 tons, Alberta 105,684 tons, and British Columbia 299,773 tons, as against a production in 1911 of: Nova Scotia 557,554 tons, Ontario 259,554 tons, Alberta 36,216 tons, and British Columbia 82,327 tons.

The quantity of coke imported during the calendar year 1912 was 628,174 tons, valued at $1,702,856, as compared with imports of 751,389 tons, valued at $1,843,248 in 1911.

### Petroleum and Natural Gas.

The annual output of crude petroleum from Canadian oil wells still continues to decline, the production having steadily fallen off during the past five years. Twelve years ago Canada produced about 50 per cent. of the domestic consumption of petroleum and its products, while at the present time not over 5 per cent. of our consumption is derived from Canadian oil wells. The output in 1912 was 243,336 barrels or 8,516,762 gallons, valued at $345,050, compared with 291,092 barrels or 10,188,219 gallons, valued at $357,073 in 1911. The average price per barrel at Petrolea in 1912 was $141.08 or considerably higher than the average price in 1911, which was $122 2-3.

The price of crude oil increased steadily through the year, rising from a minimum of $1.24 in January to a maximum of $1.65 in the latter part of December.

These statistics of production have been furnished by the Department of Trade and Commerce and represent the quantities of oil on which bounty was paid, the total bounty payments being $127,751.39 in 1912 and $152,823.29 in 1911.

The production in Ontario by districts as furnished by the supervisor of petroleum bounties, was in 1912, as follows, in barrels: Lambton, 150,272; Tilbury and Romney, 44,727; Bothwell, 34,486; Dutton, 4,335, and Onondago, 7,115; or a total of 240,935 barrels. This agrees very closely indeed with the production in Ontario on which bounty was paid, viz., 240,657 barrels. In 1911, the production by districts was: Lambton, 184,450; Tilbury and Romney, 48,708; Bothwell, 35,244; Dutton, 6,732; and Onondago, 13,501.

The production in New Brunswick in 1912 was 2,679 barrels, as against 2,461 barrels in 1911, and 1,485 barrels in 1910.

Exports entered as crude mineral oil in 1912 were 18,500 gallons valued at $3,964, and oil refined 36,945 gallons valued at $6,147. There was also an export of naptha and gasoline of 25,791 gallons, valued at $4,261.

The decreased production has been accompanied, particularly during the past two or three years, by a very large increase in imports of petroleum and petroleum products. The total imports of petroleum oils crude and refined in 1912 was 186,787,484 gallons, valued at $11,848,533, in addition to 2,144,006 pounds of wax and candles valued at $119,520. The oil imports included crude oil 120,082,405 gallons, valued at $3,996,842; refined illuminating oils, 14,748,218 gallons, valued at $1,022,735; gasoline, 40,904,598 gallons, valued at $5,347,767; lubricating oils, 6,763,800 gallons, valued at $1,077,712, and other petroleum products 4,288,463 gallons, valued at $413,477.

The total imports in 1911 were 116,892,689 gallons of petroleum oils crude and refined, valued at $6,009,730, and 1,959,787 pounds of wax and candles, valued at $106,424. The oil imports comprised crude oil, 71,653,251 gallons, valued at $2,188,870; refined and illuminating oils, 13,690,962 gallons, valued at $722,403; gasoline, 23,338,773 gallons, valued at $1,976,032; lubricating oils, 5,308,917 gallons, valued at $806,452, and other petroleum products, 2,900,786 gallons, valued at $315,973.

The principal increases in imports have been in crude oil now used so extensively in British Columbia by the railways and in gasoline.

**Natural Gas.**—While the production of petroleum has been declining, the output and use of natural gas has been steadily increasing. The southern portion of Ontario has for many years been the principal source of gas, but the Albert county field in New Brunswick is now an important producer while large developments are taking place in Alberta with such a rapid increase in output of gas that this province may soon take first place as a producer.

The total production in Canada in 1912 was approximately 15,015 million feet, valued at $2,311,126, and includes 12,534 million in Ontario, valued at $2,045,488 and 2,481 million feet in Alberta, value at $265,638. New Brunswick returns have not yet been received. The production in 1911 was reported as 11,644 million feet, valued at $1,907,678, including 10,864 million feet in Ontario, valued at $1,807,513 and 780 million feet in Alberta, valued at $110,165. These values represent as closely as can be ascertained the value received by the owners or operators of the wells for gas produced and sold or used. The values do not represent what consumers have to pay since in many cases the gas is resold once or twice by pipe line companies before reaching the consumer.

### Cement.

The statistics of production of cement given herewith, will be subject to but slight variation when complete returns shall have been received. Estimates have had to be made for two firms that had not yet reported but the totals given are probably with a half of one per cent. of the final returns. The record for the past year is of particular interest, in view of the undoubted widespread demand for cement. Congestion of freight traffic no doubt militated somewhat against the eastern mills supplying western requirements and in order to relieve the situation the Federal Government reduced the duty one-half on importations during the period from June 12 to October 31, inclusive. Statistically the important features of the industry during the year were an increase of over 26 per cent. in the Canadian output, an increase of over 116 per cent. in imports and an increase of over 34 per cent. in total consumption. Canadian mills supplied 83.2 per cent. of the consumption as against 90 per cent. in 1911.

The total quantity of Portland cement, including slag cement and natural Portland, made in 1912, was 7,169,184 barrels. The quantity of Canadian cement sold or used was 7,120,787 barrels, valued at the mills at $9,083,216, or an average of $1.27½ per barrel. The total imports of cement were 5,020,446 cwt. equivalent to 1,434,413 barrels of 350 pounds each, and valued at $1,969,529, or an average of $1.37 per barrel. The total consumption of Portland cement, therefore, neglecting a small export of Canadian cement, was approximately 8,555,200 barrels.

Detailed statistics of production during the past four years are shown as follows:

| | 1909. Brls. | 1910 Brls. | 1911. Brls. | 1912. Brls. |
|---|---|---|---|---|
| Portland cement sold | 4,067,709 | 4,753,975 | 5,692,915 | 7,120,787 |
| Portland cement manufactured | 4,146,708 | 4,396,282 | 5,677,539 | 7,169,184 |
| Stock on hand Jan. 1st. | 1,098,239 | 1,189,731 | 918,965 | 904,165 |
| Stock on hand Dec. 31 | 1,177,238 | 832,038 | 903,589 | 952,562 |
| Value of cement sold | $5,345,802 | $6,412,215 | $7,644,537 | $9,083,216 |
| Wages paid | 1,266,128 | 1,409,715 | 2,103,838 | 2,591,090 |
| Men employed | 2,498 | 2,220 | 3,010 | 3,379 |

The average price per barrel at the works in 1912 was $1.27½, as compared with $1.34 in both 1911 and 1910.

The imports of cement already included 130,580 barrels from Great Britain, 1,280,958 barrels from the United States, 6,107 barrels from Belguim, 15,857 barrels from Hong Kong, and 911 barrels from other countries.

The average price per barrel was $1.37, as against an average value of $1.26 on imports in 1911, in which year the total imports were 661,916 barrels valued at $834,879. These included 190,506 barrels from the United Kingdom, 441,317 barrels from the United States, and 30,093 barrels from other countries.

The consumption of Portland cement in Canada during each of the past five years is shown as follows:

**Annual Consumption of Portland Cement.**

| Calendar Year. | Canadian. Brls. | % | Imported. Brls. | % | Total. Brls. |
|---|---|---|---|---|---|
| 1908 | 2,665,289 | 85 | 469,049 | 15 | 3,134,388 |
| 1909 | 4,067,709 | 97 | 142,194 | 3 | 4,209,903 |
| 1910 | 4,753,975 | 93 | 349,310 | 7 | 5,103,285 |
| 1911 | 5,692,915 | 90 | 661,916 | 10 | 6,354,831 |
| 1912 | 7,120,787 | 83.2 | 1,434,413 | 16.8 | 8,555,200 |

**Annual Mineral Production in Canada Since 1886.**

| Year. | Value of production. | Value per capita. | Year. | Value of production. | Value per capita. |
|---|---|---|---|---|---|
| 1886 | $10,221,255 | $2.23 | 1900 | 64,420,877 | 12.04 |
| 1887 | 10,321,331 | 2.23 | 1901 | 65,797,911 | 12.16 |
| 1888 | 12,518,894 | 2.67 | 1902 | 63,231,836 | 11.36 |
| 1889 | 14,013,113 | 2.96 | 1903 | 61,740,513 | 10.83 |
| 1890 | 16,763,353 | 3.50 | 1904 | 60,082,771 | 10.27 |
| 1891 | 18,976,616 | 3.92 | 1905 | 69,078,999 | 11.49 |
| 1892 | 16,623,415 | 3.39 | 1906 | 79,286,697 | 12.81 |
| 1893 | 20,035,082 | 4.04 | 1907 | 86,865,202 | 13.75 |
| 1894 | 19,931,158 | 3.98 | 1908 | 85,557,101 | 13.16 |

| 1898 | 38,412,431 | 7.32 | 1912 | 133,127,489 | 18.01 |
| 1899 | $49,234,005 | $9.27 | | | |

# ADVANCE STATEMENT OF MINERAL PRODUCTION, PROVINCE OF QUEBEC*

(Figures are subject to revision)

Although there are still a few producers who are dilatory in sending in their returns of production, on the whole the responses to our enquiries are prompt and the following figures give a close approximation of the mineral production of the Province of Quebec during the year 1912.

The present statement wil be followed, in the course of a few weeks, by the complete annual report, giving corrected figures and more detailed information concerning the mining industry of the Province during 1912, as well as the report of the field-parties sent out by the Mines Branch during the summer of 1912.

In the following table, giving the value of the mineral production for 1912, a column has been added giving the value of the same products during the previous year 1911.

*From pamphlet presented by Theo. C. Denis, Ottawa Meeting, 1913.

**Table of Mineral Production of the Province of Quebec During 1912.**

| Substances. | Production 1912 Quantities | Production 1912 Value | Value in 1911 |
|---|---|---|---|
| Asbestos, tons | 111,175 | $3,059,084 | $3,026,306 |
| Asbestic, tons | 25,471 | 23,358 | 19,802 |
| Copper and sulphur ore | 62,107 | 631,963 | 240,097 |
| Gold, ozs. | 980 | 19,924 | 11,800 |
| Silver, ozs. | 26,526 | 14,591 | 11,500 |
| Bog Iron Ore, tons | ...... | ...... | 4,041 |
| Ochre, tons | 7,054 | 32,010 | 28,174 |
| Chromite, tons | ...... | ...... | 2,469 |
| Mica, tons | ...... | 99,463 | 76,428 |
| Phosphate, tons | 164 | 1,640 | 5,832 |
| Graphite, lbs. | 1,210,278 | 50,680 | 33,613 |
| Mineral Water, gals. | 39,452 | 9,854 | 65,648 |
| Titaniferous Ores, tons. | 2,949 | 4,935 | 5,684 |

| | | | |
|---|---|---|---|
| Slates, squares ....... | 1,894 | 8,939 | 8,248 |
| Cement, bbls. ........ | 2,684,002 | 3,098,350 | 1,931,183 |
| Magnesite, tons ...... | 1,714 | 9,645 | 6,416 |
| Marble ............... | ...... | 250,939 | 143,457 |
| Flagstone............ | ...... | 600 | 500 |
| Gold, ozs............. | 980 | 19,924 | 11,800 |
| Lime, bush. .......... | 1,705,937 | 455,570 | 284,334 |
| Limestone............ | ...... | 1,361,082 | 1,128,402 |
| Bricks, M. ........... | 100,146 | 1,284,232 | 1,129,480 |
| Tiles, Drain & Sewer Pipe, Pottery, etc. .. | ...... | 203,100 | 142,223 |
| Kaolin, tons ......... | 40 | 520 | |
| Feldspar ,tons ....... | 110 | 2,200 | 600 |
| Peat, tons ........... | 500 | 2,000 | 700 |
| Glass Sand .......... | 152 | 418 | 1,179 |
| Sand ................ | 81,800 | 33,200 | 62,000 |
| Quartz............... | ...... | ...... | 1,125 |
| | | $11,017,046 | $8,679,786 |

We have therefore to record an increase of $2,337,260 in 1912 as compared with 1911. For the last ten years, the record of increases of each year over the previous one has been unbroken as the following table shows.

### Table Showing the Annual Value of the Mineral Production of the Province of Quebec Since 1903.

| Year. | Value. |
|---|---|
| 1903........................... | $2,772,762 |
| 1904........................... | 3,023,568 |
| 1905........................... | 3,750,300 |

| 1907........................... | 5,391,368 |
| 1908........................... | 5,458,998 |
| 1909........................... | 5,552,062 |
| 1910........................... | 7,323,281 |
| 1911........................... | 8,679,786 |
| 1912........................... | 11,017,046 |

### Notes on Mineral Production in 1912.

#### Asbestos.

Asbestos, as in the past years, heads the list of the products of the Quebec mines in 1912. After having passed through a severe crisis, the asbestos market is steadily improving. This is specially true for the higher grades, crude and long fiber mill-stock. The demand for the short mill-stock is not brisk, and, as a consequence, the qualities under $30 a ton have to be sacrificed to some extent.

Therefore, under these circumstances, of good prices for high grade stock and low prices for short mill-stock it is quite easy to understand that only the mines which can produce the better qualities are able to operate satisfactorily. Hence, none of the mines of the Broughton district were operated during 1912, as the Broughton rock is essentially a milling rock, containing as a rule a good percentage of disseminated fiber, but short and low in value. The same remark applies to most of the mines of the Robertson district.

On the other hand, the Thetford mines and the Black Lake mines worked steadily and the shipments are higher than for 1911.

Figures of comparisons between the last three years are given below:

#### Shipments of Asbestos.

| | 1912. | 1911. | 1910. |
|---|---|---|---|
| Tons........... | 111,175 | 102,224 | 80,605 |
| Value........... | $3,059,084 | $3,026,306 | $2,667,829 |
| Aver value per ton | 27.52 | $29.60 | $33.10 |

#### Stock on Hand on Dec. 31st.

| | 1912. | 1911. | 1910. |
|---|---|---|---|
| Tons............ | 24,176 | 33,751 | 41,159 |
| Value.......... | $1,102,206 | $1,583,076 | $1,921,923 |

Returns of shipments in 1912 were received from nine operators, whereas in 1911, shipments had been effected by ten operators.

If we compare the figures for 1912 with those of 1911 we see that the shipments increased 8.75%, while the total value shows an increase of only 1.07%.

#### Copper and Sulphur Ores.

The increase in the price of copper which prevailed during 1912 as compared with 1911 naturally caused a renewal of activity in the copper mines of the Eastern townships. This was manifested by a marked increase in the shipments of copper and sulphur ore, which this year amounted to 62,107 tons, valued at $631,963 for their copper and sulphur contents; as compared with 38,554 tons, valued at $240,097 in 1911.

The McDonald mine at Weedon which is operated by the East Canada Smelting Co. is responsible for a large part of the increase. This mine is operating very satisfactorily.

The Eustis mine, another mine of cupriferous pyrite which has been in operation for 30 years, was another active shipper.

**Iron.**—For the first time in a great many years, there were no blast furnace operations in the Province of Quebec. Both the Drummondville and the Radnor furnaces remained idle all year.

**Gold and Silver.**—The gold production of the Province amounted to 980 oz. which represent a value of $19,924. The sources are the same as last year; part of this production comes from the Copper-Sulphur ores of the Eastern Township mines and the balance is the product of the operations of the Champs d'Or Rigaud-Vaudreuil, who have a hydraulic plant near Beauceville. The silver is also from the same sources.

**Titaniferous Iron Ores.**—There were 2,949 tons of Titaniferous ores shipped to the United States during 1912. These were shipped as ores of Titanium. Part came from the mines of St. Urbain, and the balance from a mine situated at Ivry, near St. Jerome.

**Mica.**—The mica market was satisfactory this year. There is a substantial increase to record as compared with the previous year. As usual the production of mica comes entirely from the Gatineau and Lievu River district, to the north-east of Ottawa.

**Graphite.**—The shipments of graphite appearing in the table of production were all made from Buckingham, which is the center of the graphite industry in the Province. However, it may be mentioned that a company is building a modern and well-equipped mill at St. Remi, Township of Amherst, some 40 miles north-east of Buckingham, which is expected to start operations shortly.

**Peat.**—The Peat Industries, Limited, made returns of shipments of 500 tons of peat fuel, valued at $2,000. This company operates at St. Brigide, near Farnham, where a very complete air-dried peat fuel plant, of a capacity of 4,000 tons a year, is installed and working satisfactorily. The demand for this fuel is quite brisk and there is no question about the possibility of disposing of a large quantity.

The summer season of 1912 was exceptionally unfavorable for the production of air-dried peat on account of the rainy weather.

**Structural Materials.**—There is a marked increase in the production of the various structural materials, limestone, granite, marble, brick, cement, etc. This is as it might be expected, as the production of these substances increases with the development of the country.

It may be mentioned that the figures given for the structural materials are far from complete, as it is almost impossible to keep track of all the small quarries and brick-yards, a great number of which only work in a desultory way.

# MINERAL PRODUCTION OF ONTARIO FOR 1912.*

| Metallic. | Quantity. | Value. |
|---|---|---|
| Gold, ozs. | 89,080 | $ 1,859,285 |
| Silver, ozs. | 30,322,805 | 17,455,080 |
| Copper, tons | 11,116 | 1,581,062 |
| Nickel, tons | 22,421 | 4,722,040 |
| Iron ore, tons | 117,357 | 238,884 |
| Pig iron, tons | 589,593 | 8,054,369 |
| Lead (concentrates), tons | 26 | 1,290 |
| Cobalt oxides, etc., lbs. | 1,029,532 | 317,165 |
| Nickel oxides, lbs. | 117,160 | 11,716 |
| | | 34,240,891 |
| Less Ontario ore smelted into pig iron, 71, 589 tons | | 145,326 |
| | | 34,095,565 |
| **Non-Metallic.** | | |
| Arsenic (refined), lbs. | 3,927,347 | 79,297 |
| Brick, common | 385,000,000 | 3,178,250 |
| Tile (drain) | 16,463,000 | 279,579 |
| Brick, paving, fancy, etc. | 5,631,000 | 126,286 |
| Brick, pressed | 65,028,000 | 627,669 |
| Building and crushed stone | ......... | 953,839 |
| Calcium carbide, tons | 1,998 | 120,000 |
| Cement, Portland, bbl | 3,028,486 | 3,373,653 |
| Corundum, tons | 1,960 | 233,212 |
| Feldspar, tons | 12,133 | 24,416 |
| Graphite (refined), tons | 1,246 | 65,076 |
| Gypsum, tons | 31,331 | 50,246 |
| Iron pyrites, tons | 20,677 | 70,694 |
| Lime, bush. | 2,297,525 | 381,672 |
| Mica, tons | 318 | 36,634 |
| Natural gas | ......... | 2,267,897 |
| Peat, tons | 175 | 725 |
| Petroleum, Imp. gals | 8,432,730 | 344,537 |
| Pottery | ......... | 52,445 |
| Quartz, tons | 94,758 | 179,576 |
| Salt, tons | 90,986 | 450,251 |
| Sewer Pipe | ......... | 427,353 |
| Talc, tons | 5,902 | 53,118 |
| Total non-metallic production | | 13,376,425 |
| Add net metallic production | | 34,095,565 |
| Total production | | $47,471,990 |

### General Remarks.—Metals.

**Gold.**—For the first time in the history of Ontario there was a substantial production of gold. In 1911 the output had a value of $42,637; in 1912 of $1,859,285. The explanation is found, of course, in Porcupine, where the mines came into yield during the year. The Hollinger and Dome are the leading properties, and furnished the bulk of the production, but there are a number of smaller mines, several of which contributed to the yield, and others whose stamp mills are not yet completed and in operation. This group comprises the McIntyre, Vipond, Jupiter, McEnany and others. An unfortunate labour strike ocured in November, and to some extent lessened the output of bullion. In other gold districts such as Swastika, Larder Lake and Munro-Guibord, a good deal of development work has been done, but the era of steady production has not yet set in. At Long Lake, the stamp mill has been waiting for power, now nearly ready for delivery. The St. Anthony mine at Sturgeon Lake and the Cordova mine in Peterborough county both yielded considerable bullion.

**Silver.**—Cobalt well maintained its rate of production, the output of silver being a little over a million ounces less than in 1911. Owing, however, to the higher prices for silver, the money return to the mining companies was greater by about one and a half millions of dollars. It would appear as if the crest of production at Cobalt were reached in 1911, and that the descending curve brought the output in 1912 to nearly the same level as in 1910.

The total production since the opening of the mines has amounted to nearly 156 million ounces, and the total value to about 82 million dollars, as follows:

| Year. | Ounces. | Value. |
|---|---|---|
| 1904 | 206,875 | 111,887 |
| 1905 | 2,451,356 | 1,360,503 |
| 1906 | 5,401,766 | 3,667,551 |
| 1907 | 10,023,311 | 6,155,391 |
| 1908 | 19,437,875 | 9,133,378 |
| 1909 | 25,897,825 | 12,461,576 |
| 1910 | 30,645,181 | 15,478,047 |
| 1911 | 31,507,791 | 15,953,847 |
| 1912 | 30,260,635 | 17,455,080 |
| Total | 155,832,615 | 81,777,260 |

The tendency towards final treatment of the ore in the camp is manifested in the increased shipments of bullion, consignments of which amounted to 5,071,897 ounces in 1912 as against 3,132,976 ounces in 1911. The Nipissing and Buffalo mines are now equipped for reducing their entire output to merchantable bars on the spot. Nevertheless, the tonnage of ore and concentrates shipped to outside points was larger than in 1911, the respective quantities being 17,959 tons ore and 11,214 tons concentrates, as compared with 17,278 tons ore, and 9,375 tons of concentrates in 1911. The year of largest shipments was 1910, when 27,437 tons ore and 6,845 tons concentrates left the camp.

The largest producers during the year were as follows:

| | Ounces. |
|---|---|
| Nipissing | 4,680,670 |
| Coniagas | 3,703,942 |
| La Rose | 2,920,344 |
| Crown Reserve | 2,714,765 |
| McKinley-Darragh Savage | 2,694,560 |
| Kerr Lake | 1,895,309 |
| Buffalo | 1,890,150 |
| Cobalt Township | 1,505,396 |
| Temiskaming | 1,217,994 |
| O'Brien | 1,091,631 |

*Presented at the Ottawa Meeting.

In Gowganda three mines—Miller Lake. O'Brien, Millerett and Mann—produced in all 549,976 ounces, and in South Lorrain one—Wettlaufer-Lorrain—834,-119 ounces. The T. & N. O. railway branch line from Earlton to Elk Lake is now in operation.

As in previous years, the larger proportion of the high-grade ore and concentrates produced at Cobalt was treated in refineries situated in Ontario, the principal works being those at Copper Cliff, Deloro, Thorold and Orillia. At Deloro and Thorold, also at a small refinery opened during the year at North Bay, the oxides of cobalt and nickel are produced and large shipments made, both of refined cobalt oxide and of the mixed oxides and of the mixed oxides of cobalt and nickel, to the United States and European markets. Another by-product turned out by the refineries is white arsenic, of which nearly four million pounds were made during the year.

There was paid out in dividends by silver mining companies in the Cobalt camp over seven million dollars in 1912. The total distribution of profits since the beginning of the camp has been close upon 41 millions of dollars on a gross aggiegate return for sales of silver of $81,777,260.

New and important silver-bearing veins were found at La Rose, Cart Lake (Seneca Superior), Casey Cobalt, etc. The last named mine is significant of the possibilities of the conglomerate, situated as it is, on an outlier of this formation some 14 or 15 miles distant from Cobalt proper. The finding of good ore by the Beaver mine in the diabase underlying the Keewatin, and the recrudescence of the Cobalt Townsite mine were other features of the year.

**Platinum and Palladium.**—It is well known that platinum is associated in small quantities with the chalcopyrite in the nickel-copper ores of the Sudbury district. Accompanying the platinum is palladium, a silvery-white metal of the same group, which finds its chief uses in the manufacture of astronomical instruments, watch-making and dental work. There were recovered by the Orford Copper Works, New Jersey, in refining the nickel-copper mattes produced at Copper Cliff during the six years 1907 to 1912 inclusive, 2,864 ounces of platinum and 4,896 ounces of palladium, together with 15,675 ounces of gold and 459,250 ounces of silver. It cannot be specifically stated that tihs entire production was from the nickel-copper ores, since certain residues from other mines are treated along with the matte in the process of refining. Doubtless, however, a large proportion is traceable to the nickel and copper-carrying pyrrhotite. The value of the production was about $817,030.

**Nickel.**—Leaving out of account the nickel constituents of the ores raised from the silver mines of Cobalt, the production of nickel in 1912 amounted to 22,421 tons, being 5,372 tons, or 31.5 per cent., in excess of the production of 1911. There were 725,065 tons of ore smelted, the matte produced aggregating 41,925 tons. The mines operated by the Canadian Copper Company were Creighton, Crean Hill, and No. 2, and by the Mond Nickel Company, Victoria No. 1 and Garson. About 2,000 tons of ore were treated by the latter company from the Alexo mine, a new deposit in the township of Dundonald on the Temiskaming and Northern Railway, now being opened up.

Systematic and extensive operations with the diamond drill by the several companies in the Sudbury region have proven the existence of very large reserves of nickel ore. At the Murray mine, the Dominion Nickel Copper Company discovered a large body of ore some distance away from the outcropping of the former workings; at the Frood mine, the property of the Canadian Copper Company, the drill revealed what is believed to be the most extensive body yet discovered; and the Mond Company have located an extension of the Frood on their side of the boundary line. The Dominion Company, which had large holdings on the Northern Nickel range, including the Whistle mine, after acquiring the Murray mine, formerly owned by the Vivians, and the Gertrude and Elsie mines, which belonged to the Lake Superior Corporation, have sold out to a new company, said to represent the Rothschild interests. The prospects are for a large expansion in nickel mining in the near future.

**Copper**—Copper was produced to the extent of 11,116 tons, almost wholly from the Sudbury district, where it occurs associated with nickel. The output for 1911 was 8,966 tons, the increase for the year being about 24 per cent.

**Iron Ore and Pig Iron.**—The quantity of iron ore mined in Ontario in 1912 was less than in 1911 by 58,-274 tons. Shipments were from the Moose Mountain, Helen and Bessemer mines. The Grondal concentration plant at Moose Mountain and the roasting equipment at the Magpie mine (Lake Superior Corporation) are now both nearly completed, and if successful in practice will inaugurate the utilization of the low-grade iron ore deposits of the Province.

Of Pig Iron the output was 589,593 tons, as against 526,610 tons in 1911. The number of blast furnaces in operation was eight, as follows: Algoma Steel Company, Sault Ste. Marie, 3; Canada Iron Corporation, Midland, 2; Steel Company of Canada, Hamilton, 2; Standard Iron Company, Deseronto, 1.

## Non-Metals.

**Building Materials.**—The building trade was brisk in the cities and towns of Ontario, and there was an increased output of construction materials as compared with 1911, notably in brick and stone, also a small increase in Portland cement. Lime showed a falling off. The beautiful marbles afforded by the quarries at Bancroft are coming into use for decorative purposes, especially in public buildings. Trap rock is also quarried in Hastings county and used in the making of good roads near Toronto and elsewhere. The whole production of building materials amounted in value to $8,-641,369.

**Petroleum, and Natural Gas.**—The yield of petroleum again shows a decline, the quantity raised from the wells of Lambton and Kent counties being 8,432,730 Imperial gallons as against 10,102,081 gallons in 1911. Natural gas shows an increase, the output in 1912 having a value of $2,267,897 as compared with $2,186,762 the previous year.

**Minor Products.**—There is a long list of mineral substances produced in Ontario, none of them of prime importance, yet contributing to the aggregate output, and constituting the basis of considerable industries. Among these are corundum, which shows an increased production in 1912 of $86,504; graphite, increase $28,-711; iron pyrites, decrease $47,763; mica, decrease $6,-424; pottery, increase $1,945; quartz, increase $115,171; 584; feldspar, decrease $27,194; gypsum, increase $1..-salt, increase $19,416, and talc, increase $5,393. In most cases the raw material is abundant and could easily respond to a much larger demand.

# THAT NELSON PLATINUM, MR. FRENCH, AND SOME FACTS

We have been desired to publish the following letter. We do so without comment.

21st February, 1913.

The Honourable
The Minister of Mines,
Victoria, British Columbia.

Sir,—I beg to report as follows regarding my investigations into the alleged finding of platinum metals of that group in certain dykes in the vicinity of Nelson.

Last year I had a number of samples sent to me; these I sent to several eminent chemists for assay, all of whom reported that they were unable to detect even a trace of platinum metals of that group in the samples tested.

These results were published in detail in the report of this department for 1911—pages 165. et seq.

On October 1 of 1912, I proceeded to Nelson—at your request—to obtain other samples from the same and other localities, so that our samples would represent a wider range.

I made you a detailed report of my trip to Nelson, under date of December 18, 1912, which may be briefly summarized as follows:

I personally took the following samples, with the assistance of Mr. James McGregor, inspector of mines, and in the presence of the parties interested:

No. 7201—Devlin dike; general sample, upper and softer portion of dike;
" 7202—Devlin dike; general sample, lower and harder portion of dike;
" 7203—Patenaude dike; general sample, across dike;
" 7204—Patenaude dike, special sample of 2 feet next to contact;
" 7205—Beelzebub dike, Granite-Poorman Mine, general sample;
" 7206—Beelzebub dike, Granite-Poorman Mine, special sample of footwall.
" 7207—Greenhorn dike, Granite-Poorman Mine, general sample;
" 7208—Granite dike, Granite-Poorman Mine, general sample;
(It was from this dike that the 50 tons milled was taken.)
" 7209—Hardscrabble tunnel, No. 1, chute, general sample of dike.

In addition to the samplings made by me personally, the following samples were supplied to me:

" 7211—Monaghan dike, general sample, sampled by owner;
" 7212—Monaghan dike, general sample, 2 ft. next hanging wall, sampled by owner;
" 7269—McQuarrie & Robertson dike, samples supplied by owners.
" 7215—Sample given by Thomas Gough, manager Granite mine, to the Provincial Mineralogist and said to be a sample from "concentrates" made on Wilfley table, in 1911, during a run through the Granite mill of 50 tons of dike matter, taken from same dike as was sample No. 7208.

As the ratio of "concentrates" to the ton of ore is unknown, this sample would not determine the amount of metal in the dike, and was taken only to determine whether there was any platinum present even in ore so concentrated.

It was Mr. A. G. French who was primarily responsible for the alleged discovery of platinum, and I found in an interview I had with him that he claimed that the metals of the platinum group "were so elusive that no ordinary assayer, even the best, could find them upon assay, but that he (Mr. French) by his great experience had found a method of assaying that would show them."

I obtained from Mr. French a description of his method of assaying, which I had typed, and submitted a copy to him for correction; this was returned with slight corrections and initialled by him.

To show me the manipulation of his processs, Mr. French had some samples run through in my presence; those on dike matter were, however, abandoned, but a sample of concentrates was run through to the end.

The samples, re-agents, and operators were of Mr. French's selection, which was unimportant, as it was only the manipulation I was there to see, and the result was of no consequence, as of course I could not certify the results without control of operations.

Upon my return to Victoria, I had the samples I had obtained divided each into several identical samples.

There has never been any question as to the samples or sampling—the whole question has been as to the assaying of the samples, so to obtain the best expert determination on this point, I sent a set of four samples, each set identical, to a number of the most expert chemists, asking that they be "tested with the greatest possible care for metals of the platinum group, for even a trace, and if found, then in what quantities."

With each of these sets of samples I sent a copy of Mr. French's method of assaying.

Sets of samples were sent to the following parties, each set being identical and comprising Nos. 7203, 7205, 7211 and 7215:—

Canadian Government Bureau of Mines, Ottawa, courtesy of Dr. Eugene Haanel; this laboratory does all the chemical work of the Bureau of Mines and of the Geological Survey of Canada.

Johnson—Matthey & Co., London, England, Assayers to the Royal Mint, one of first authorities in England on Platinum assaying.

Dr. Frederic P. Dowey, Washington, D.C., chief Chemist to the U. S. Mint and the greatest authority in America on detection of minute quantities of platinum, the author of numerous papers on this special subect. (These were sent through the Geological Survey, whose courtesy and Dr. Dowey's is hereby acknowledged.)

Ledoux & Co., of New York, one of the best known assaying firms in America.

Consolidated Mining & Smelting Co.'s laboratory at Trail, whose chemists have become expert in this matter.

British Columbia Government Laboratory, Mr. Carmichael and Mr. Whittaker working independently, making two sets of assays.

The S. S. White Dental Company, manufacturers of platinum goods, New York.

With the notable exception of the S. S. White Dental Company (which will be remarked on later), each and every one of these experts to whom the question had been submitted reported that they were unable to find even a trace of any metal of the platinum group.

The following are extracts from some of the letters accompanying the certificates of assay:—

Johnson-Matthey & Co: "Our results are again of an absolutely negative character, and we can affirm that the samples contain neither platinum nor metals of the platinum group."

Dr. Dewey reports:

"Washington, D.C., Jan. 21, 1913.

"The Director of the Mint:

"Sir,—None of the samples from the Provincial Mineralogist of British Columbia, forwarded to us by the United States Geological Survey, show any platinum.

"No unusual occurence was observed during the assay, but no special test could be made for Canadium."

"Respectfully,

((Signed) "Frederick F. Dewey,

"Assayer Bureau of the Mint."

Ledoux & Co: "In examining these samples we have used assay charges four times as large as usual, and the results are negative in every case; we can assure you that none of these samples contain even a trace of platinum or any other members of the platinum group.

"We have assayed these samples by the method described as A. Gordon French's method, a sketch of which accompanied your letter."

Mr. Carmichael and Mr. Whittaker—In addition to the four samples mentioned also assayed each and every one of the samples brought from Nelson.

Mr. Carmichael says: "These assays were made with the greatest care, both by the assistant assayer (Mr. Whittaker) and myself personally, and I must now report that in no case were we able to find even a trace of platinum or any of the metals of the platinum group.

"The samples were tested both by Mr. French's method and by the generally accepted methods, and as a result, I am certain they do not contain any of the platinum group metals within the limits stated, that is, not as much as one ten-thousandth part of an ounce to the ton.

"To test whether there was even an 'infinite simally minute' quantity of platinum present, as is frequently found in the gold of this coast, we ran through the furnace, by Mr. French's method, 60 charges of 20 grammes each of sample No. 7215, 'concentrates,' equal to 1,200 grammes of material, combining all the buttons into one in the final cupollation.

"We next took 42 charges of 1 A T (29.,166 grammes), making 1,225 grammes of materials, which we ran through by the regularly adopted methods joining all the beads into one on the final cupollation. These two beads were treated separately, and any possible platinum condensed into a solution of about 1/20 c.c. in volume, and each of these solutions tested qualitatively, by potassium iodide, showed the presence of platinum 'in infinitely small quantity'—as near as possible to estimate, I should say the platinum present amounted to about sixteen (16) cents worth of platinum in 10,000 tons of ore, an amount quite negligible and only discernible upon treating a great amount of material—more than 1,220 grammes.

"I have carefully looked into the method of assay as proposed by Mr. French, and have experimented with it, and I fail to find any merit in it, either from a chemical or practical viewpoint."

The S. S. White Dental Company—as already noted—report that they find platinum and gold in each of the four sample sent them, as follows:—

Sample.

No. 7203—Platinum, 0.033 oz.; gold, 0.035 oz. per ton;

" 7205—Platinum, 0.088 oz.; gold, 0.108 oz. per ton.

" 7211—Platinum, 0.042 oz.; gold, trace

" 7215—Platinum, 0.119 oz.; gold, 1.136 oz. per ton.

The company, as such, has a high commercial standing, but of the skill or experience of the assayers employed by the company, I have no means of judging. The company, however, is engaged in the manufacture of platinum goods on a large scale and its laboratory is naturally an adjunct to its manufacturing business, so that it is quite possible, and even probable, that its laboratory—and even utensils—were so saturated with platinum as dust and otherwise, as to render any samples treated there open to grave suspicion of contamination and the results subject to question.

The firm does not do assaying or chemical analysis as a business—although in this case it was paid for these assays—and has no public rating as analysts. My only reason for sending samples to this firm was the fact that a number of person in Nelson had received from it returns of platinum in these dikes, and it was largely due to these assays that local credence was given to the alleged discovery, and that this "platinum excitement" was started.

Some years ago we had an experience with another firm of platinum manufacturers—near New York—who reported to prospectors high platinum results in ore, which subsequent investigations proved to be not founded on fact; this was accounted for by contamination in the laboratory of the platinum works, the probability of which, in such a laboratory, is known to any assayer of experience. In fact, it is usual to exclude all bullion assaying from the room in which assays of ore are made.

In making this investigation I have simply obtained the samples and Mr. French's method of assaying. These I have submitted for the best expert advice obtainable, and in making this report to you of the result of the investigation, I do not need to express any opinion of my own. I merely give you the verdict of the experts employed, which may be summarized as follows:—

Seven of the most expert assayers in England, the United States and Canada—including the Geological Surveys of the two latter countries—report that not even a trace of platinum is present.

The laboratory of a firm of platinum manufacturers reports from 0.033 (33-1000) to 0.088 (88-1000) oz. per ton on dike samples and 0.110 oz. per ton on the "concentrates.

Any comment on the above results appears to me to be unnecessary.

I am, sir, respectfully,

(Signed) Wm. Fleet Robertson,

Provincial Mineralogist.

# THE GEOLOGIST.†

(Written for the Annual Meeting of the Canadian Mining Institute, by H. E. T. Haultain.)
Ottawa, 1913.

For the sixth year in succession the president of the Canadian Mining Institute is a geologist. Ontario has its Provincial Geologist and British Columbia its Provincial Mineralogist, and the Dominion its Geological Survey. These are all of importance to the community. The standing of the geologist in all branches of his activities, and they are varied, is taken as a matter of course. In a public way it is neither questioned nor criticized. So quietly and universally is this the case in Canada that the half brick** that the spur of the moment caused me to throw at the action of certain geologists last March had all the appearance of a bombshell. Judging from the many comments during the past year it must have shattered into its original grains of sand and these must have found lodgement in many tender spots wide of the original line of aim. But though my brick was fashioned on the spur of the moment (and hence lacked sufficient coherence) it represented a feeling that has been growing and is sane and sound.

The geologists are a large group and count among their numbers men eminent in the community. Their general average is high. They touch on the one hand ultra-academic learning and on the other the popular progress of the country. Owing to their special field of research they are segregated. They are more or less separated by gulfs from other scientific men and are in a position to present a united front, which in itself is sufficient to deflect criticism or attack. But in addition they are surrounded, they surround themselves individually and collectively, by one of the finest assets of defence, a well-carried dignity. Furthermore, they are coming this summer to this country from all over the world, and to a very large part of the community they will appear of magnificent importance. They will be our guests and we shall be their hosts, carrying all the responsibilities that are entailed thereby. One may well hesitate before criticizing.

Nevertheless, there are aspects of the case that should be considered, and I hope to put before you certain ideas that may call forth profitable discussion. Succinctly, but perhaps crudely, geology is the science of rocks and mineralogy the science of minerals. Minerals are the basis of the mineral industry and minerals are found in rocks, hence the syllogism is apparently complete. Geology and mineralogy are the basis of the mineral industry. This is such a fine, comfortable, broad generalization that it is commonly accepted for very much more than it really means.* It would be as well to confess at once that this is the source of any peevishness, and of the tender spot, the irritation of which last March caused the throwing of the brick. Into the details of this phase of the matter this is not the time or place to enter.

The early reports on the geology and mineralogy of the Cobalt district issued by the Ontario Bureau of Mines were a model of utility. Cobalt is a remarkable case. Perhaps there is no other metalliferous camp in which the commercial values are so clearly and so simply affected by geological conditions to the degree that exists in Cobalt.

The early recognition of this, the publishing of it in clear, unmistakeable manner, so that the early prospectors and miners could understand was a magnificent piece of commercial geology applied to metalliferous mining.

Should the various geological departments throughout the Dominion fail to achieve the like of this again in a generation, still their existence would be justified by a possibility of this alone.

In this particular case the geologist could and did "see into the earth farther than the ordinary man." He could foretell with fair accuracy the extensions of the contacts and thus, in many cases, foretell definitely the commercial conditions at depth. This probably lent added local importance to geology, and geological conditions become a very important feature of all reports on mineral properties. Alleged geogicial features and broad conclusions supposed to be derived from them became a prominent part of all newspaper boom talk, and of all the wildcat reports with which the community was flooded. Many men with a smattering of geological knowledge and some geologists with little or no experience either geologically or com-

†Editor,s Note: This paper is intended by Mr. Haultain to be one of the series on "Toronto University and the Mineral Industry.

**See "The University of Toronto and the Mineral Industry." Part II., Canadian Mining Journal. August 1, 1912. Page 510.

mercially with mining, posed as experts. Geological nothings were learnedly interpreted into optimistic reports and drew out much money and many failures. Should all this be laid at the door of the geologist? Certainly not. It is characteristic in greater or less degree of every mining boom. But it existed here, I think to a greater degree than usual, and with a very few, perhaps notable exceptions, geologists let it pass without comment, while others helped it and fanned it, possibly unwittingly, by their serious and seemingly important discussion of hopelessly unimportant academic details. These remarks are by way of being very general. They are perhaps not specific or explicit enough to provoke a profitable discussion. That particular phase of the subject does not lend itself to explicitness. It is a matter of degree. Every man must decide for himself to what extent there was posing and what was probably the motive of the posing. But I will try to be specific and, to many, the explicitness will be so obvious that they may not accept it as a subject for discussion.

Is it too simple to assert that a geologist is not, as a consequence of his geology, a mining engineer? Yet there are those who claim that geology is such a large part of mining that a geologist is as a result a mining engineer. The truth is that a mining engineer is to a large extent a geologist. He concerns himself deeply with his branch of geology. He knows much geology and studies much of such geology as applies to his work. The geologist knows much more geology and studies it more intensely, but their points of view are very different. A geologist may have spent years mapping mining districts, and yet not be a mining geologist. He may be a very valuable man at mapping the district and yet be quite unsuitable to report on the value of an ore body. A man may be a keen and successful student of the life history of certain phases of ore deposition and yet not be a suitable man to estimate the risk involved in opening up an ore body. A man may be a renowned histologist or anatomist and yet be a very poor judge of a man. The botanist plays a small part in our lumbering interests. Our chemists and druggists are not physicians. Bacteriologists do not report on sewage disposal, and our physicists, with all their profound knowledge of gases, neither design gas engines nor become aeroplanists. In fact such is generally the case. The point of view is so different that the man who is keen on the scientific side is handicapped if he enter the commercial side.

A geologist cannot become a mining engineer, cannot become the right man to report on a commercial proposition (that is to estimate a risk) without a special and lengthy training, which he can get only in actual mining operations. A geologist can no more become a mining engineer by simply saying so than can a new graduate of a mining course in a university. Each has a good training, enabling him to become a mining engineer through experience, but of the two the new graduate is nearer the goal on account of his flexibility and on account of his broader perspective.

Some geologists do become mining engineers; we have notable examples, but it is by means of experience in actual operations.

On the other hand all mining engineers must have considerable geological knowledge, their paleontology may be weak or practically non-existent and their optical crystallography likewise, but their working knowledge of ore deposits is not only general and broad, but of useful phases it will be detailed and intimate.

The average mining engineer knows much more about ore deposits than the average geologist and what is very much more important, his point of view is quite different. Two Porcupine veins may have a similar life story and be each of intense interest to the geologist and may be the subject of unending dissertations, but one may be very valuable commercially and the other worthless without in any way affecting the interest of the geologist. Speaking broadly, the quartz is the main source of interest to the geologist, the gold to the engineer. There are those, however, who like to say that because the engineer's eye is on the gold he sees nothing else unless a geologist comes along and interprets things for him.

For the engineer there are many basic sciences—geology is only one of them. Mathematics is as much a basic science. Mining engineering without geology is impossible; it is also impossible without mathematics, but the mathematician is no more a financier than is the geologist a mining engineer. It is the function of the engineer to co-ordinate the sciences to a definite end. The mining engineer estimates risks, and to do this he must balance up many things of which geology is only one. The mining engineer gets results which call for co-ordination of knowledge of different branches of science, and calls for compromise.

To question the value or importance of geology to mining would be foolishness of a very inane kind. It would be fully as foolish as to question the value of arithmetic, but much geology has as little to do with mining as have quanternians.

To our more important geologists this is obvious, but there are those who would foster the other idea and there is indeed abroad in Canada a false idea of the real importance of geology to mining.

The mining engineer needs the geologist. He appreciates the geologist and his stories better than can anybody else, and he can make more real use of the geologists' knowledge than can anybody else. The geologist has the time and opportunity and the conditions that permit him to study geological problems as pure scientific problems. He can stop and carefully study the effect of varying conditions of high temperature, of chemical reaction, or time, of capillarity, and of many more or less obscure conditions, and with his study he can often tell us with rough accuracy the life history of some of our ore bodies, he can in truth be an authority "on an almost absolutely unknown region." What really magnificent stories the geologist has told and can tell the mining engineer. Has any engineer ever been told a more beautiful story than that of magnetic segregation or of metasomatic replacement, and is not the whole subject of magmatic waters, magnificent inspiration to thought and spur to greater study? But some geologists are about to forget that this is only a part. They are inclined to think that the life story of an ore body is everything or nearly everything, whereas the engineer recognizes that it is only a part and often a very insignificant part of what is really required, for often it helps him no more in relation to his desired result than does his mathematics or his physics. Many geologists are apt forget that all that is known under the headings of geo-chemistry and geo-physics do not but touch matters of vital importance to the engineer. There are generally other causes and facts of much greater importance to the engineer and to the community. There are causes and effects not yet classified, with only a generic name, and that probably a false one. The causes giving the most important features of an ore-body are causes not required, not considered, not included in the stories of the geologist, but to the engineer they are paramount, they are the causes known as chance. That the source of a river is higher than its mouth is due to the very well-studied laws of gravity, but the twists and turns of the river, its falls and its navigability are the results of chance. An ore body may clearly be the result of magmatic waters, but whether a particular part will carry $2 or $20 worth of mineral is a matter of chance; is a matter of so many varying causes that no geology can follow them.

Once in a while geology can give us very definite information not on the varying values but on the limitations of extensions of our ore body.

In general the training of the geologist dealing as it does with broad generalities, with life histories, with generalizations rather than with detached facts, gives him a perspective that is a serious obstacle when he tries his hand at estimating the commercial risks of ore bodies. It is not profitable though it would be easy to be specific here; many of us carry in memory and some of us on our files, examples of this kind of thing.

But enough, the work of the geologist is of certain value to the mining engineer, but as far as mining and the estimation of mining risks is concerned the work of the geologist is for the engineer. The geologist is a scientific specialist, the engineer is the co-ordinator. The geologist cannot become a co-ordinator without special training which entails actual experience of operations, and geology is only one out of may things that the engineer has to consider. It is often, in metalliferons mining very often, of a type that the engineer takes in his daily stride as it were.

This much must be sufficient concerning the relation of the geologist to the engineer, the discussion will I hope carry it further.

There is another phase upon which I must touch and that is the relation of the geologist to the community. Not only have the three last presidents of the Canadian Mining Institute been geologists, but the president of the American Institute of Mining Engineers is a geologist, the Dean of the Faculty of Applied Science of McGill is a geologist, the late renowned Principal of McGill was a geologist. Van Hise is President of the University of Wisconsin and Geikie is president of the Royal Society. We find geologists holding important public positions in all parts of the world and holding them successfully and with distinction. The geologists are an ancient and honourable body. I can find no reference of slur or suspicion remaining attached to them. They have been clean and kindly men. Taking the geologists that I know personally I find them delightful men, agreeable companions and general favourites wherever they go. Of course there is always the exception that proves the rule, but I believe you will all agree with me when I say that in general pleasantness the average of the geologists is higher than the average of most of the other groups of men with whom we come in daily contact. They are not only prominent in their scientific work, but they are prominent in the community, and the Canadian public at large accepts them not only as being of great importance to the state scientifically, but as being above the average good citizens.

In remarkable contrast to these public successes of the geologist, I find the condition of the engineer, not only the mining engineer, but the engineer in all branches. The engineer is doing the world's best work to-day. All that counts for prosperity and health and material growth is based on the work of the engineer. All that we are most proud of in this young nation is dependent upon the work of the engineer. The engineer exists in large numbers. Even in Ottawa there are more engineers than geologists. But we find very little public recognition of the engineer. We seldom if ever find him holding a public position of responsibility or honour outside of his immediate work. We have no engineers in Canada who are members of the Royal Society, and if we have one who has been knighted it is simply the exception that proves the rule. Why? How is it that the geologists beat the engineers to the high positions? Is it because their work is of greater importance to the state? Is it because their work is of a higher type? One would think so from the results. Is it not patent? Is it not obvious? But unfortunately the truth is not always obvious. Truth is oftener at the bottom of the well than prominent on the horizon. We must carry our analysis further. I submit that there is another and simpler reason. When we analyze the work and effort of the geologist we find it made up of two separate and distinct functions. The engineer's time and effort is devoted entirely to his engineering work. A part only of the geologist's time is devoted to the study of geology. A large part, and some times the larger part, is devoted to descriptions of his work, to publicity. One of their functions is that of the story teller. From the beginnings of their existence they have been great story tellers. In fact, they have been the champion story tellers of all time. Now there is no doubt in my mind that some geologists, or near-geologists, will consider that this is another half brick in poor disguise. But let us see what the story teller has been to the community. When we go back to the beginning of things, that is to the beginning of things for man, to about the time, let us say, of pithecanthropus erectus, the story teller was beginning. He was almost the first luxury. Possibly man's first distinction was that he was a fire-using animal. Certainly about the same stage of his development he became a story-telling and a story-bearing animal, and the story telling part was certainly more removed from mere animal than any other phase of his activities. Progress in all stages has been based largely on co-operative organization and this came first with the fighting animal, but organization alone did not win out from the animal stage. Organization could and does exist without language and without man, but we departed from the animal through language and progressed through language. Language was produced by and for the story teller. For his purpose was language developed and without language we would have had no modern man. The neolithic scriber on bone, that "mamothistic etcher at Grenelle" was a later development of the story-teller, who told stories in pictures and was not only the forerunner of the comic supplement, but of all that we understand in modern pictorial art. Later he told stories in song and in mimicry so that all our art, which represents our greatest departure from the anthropoid ape is the work of the story teller. He has been in the vanguard of all progress since we left the trees.

It is impossible to conceive of a geologist being eminent without this story telling function being well developed. Unlike most story tellers he generally tells his own story of his own work. He is his own publicity agent, and what magnificent stories he has been able to unfold. In the second chapter of Genesis and the second verse, we are told that God rested on the seventh day and for a thousand years man had interrupted all his work every seventh day to signify his assent to the six day history of the world's creation. The story telling geologist comes along and says: "There is a mistake somewhere; it took several million years to create this earth and I can prove it, here are the proofs." When the world had become accustomed to the shock of this the geologist's story went on to tell that man was not created on the sixth day, but that his creation was a gradual development occupying a period also of millions of years, the records of which in an almost unbroken chain stretching from the protozoa to modern man aré preserved in the everlasting rocks. True some links were absent, but every now and then the story is added to and the Neanderthal skull and our friend from Java help to fill in the blanks. Who couldn't attract attention and hold the stage with such stories as these? And the geologist had many such in his bag. He shows us where the moon was born. He dissects the teeth of the mammoth who wandered on our back yard before the ice was two miles thick upon it and he counts the nervatures of the wing of the fly that plagued it.

But even the geologist's supply of stories could not keep up forever to these high-grade samples and as the family of geologists grew they had to be content with less and less interesting stories. But stories they must have to maintain their eminence and a story to be a story entails of necessity a hearer, a willing and an interested listener. As the quality of his stories waned he often had to expend as much pains finding the listeners as in finding the story, and this led him to the study of the listener, to the study of man, his characteristics, his wants, his needs, his foibles, and his weaknesses. He had to make the most of meagre stories, he had to study that phase of man which brought him listeners. This has ben going on for generations and the methods of the family of geologists in finding hearers is as well organized to-day as their study of geology. Are not many of them geologists in the summer and writers of their stories in the winter?

Now the story teller is still the greatest man among us. What does Kipling get per word? and has he not had the refusal of the high honours of the realm? Theodore Roosevelt received $350,000 for seven years' work as President of the United States, but received a million dollars for the story of his African holiday. But the geologists' stock of interesting stories is running low or rather the proportion of interesting stories to the number of geologists is becoming small, and instead of a greedily paying public he must perforce fall back on government Bluebooks for publication.

And how do I interpret all this? I interpret it thuswise. The work of the geologist is in two parts. There is the study of geology to get the story and of man to get a listener. The engineer is so busy with his own work that he fails to study man. The geologist, with his knowledge of man and with his knowledge of publicity becomes useful to man in other ways.

The search for a listener has made the geologist in many ways a broader and a bigger man and his art of story telling brings him into the public eye.

Do I begrudge the honours to the geologist who has reached to high position through his knowledge of man? By no manner of means. I respect him, in some cases I bow down to him, but let us be honest about it and recognize that it is not the geology, but the story telling and the man that has won to high honour.

Why then my half brick of last year? It was not directed at the geologist as a geologist or as a story teller but at men who were inclined to tell stories of no consequence to listeners provided by the reputation of the whole family of geologists and to make capital out of these stories of no consequence. The geologist has from time immemorial been on a pedestal, and has no doubt taken care to be kept there. Round and about him due to his art of story telling there has been a halo or an auro. His stories have not only had the important essentials of mystery and distance, but, in the main, they have been truthful and unquestioned by the general public. But there are those who would impose on this good name and on this long-earned and carefully preserved reputation.

I must confess that it is a source of some content to see the radical change that has taken place in our programme since last year, with the greatly reduced percentage of geological papers. There are many geological stories that we require, but that fact need not be abused.

This summer the geologists from all the world are coming here, and they will bring with them their best stories, and we, aided by government grants, have been diligently preparing for them not only to hear their stories, but to provide them with new stories.

Their stories will be lstened to by all manner of people, but by no one will they be more appreciated than by the mining engineer, for he will know and will preserve what he needs and this he will use in practical work for the benefit of the community and, going his own way, he will hold his peace and be unrecognized, and to the geologist and to the story teller will be the glory.

. . . . . . . . . . . .

### Discussion of Mr. H. E. T. Haultain's Paper on "The Geologist."

Remarks by Mr. R. W. Brock, Director the Geological Survey of Canada.

Mr. Haultain's remarks at the C.M.I. meeting last year were jocular and, therefore, called for no serious rejoinder. Moreover they were restricted to certain geologists and would be equally applicable to certain mining engineers or certain men of any other profession. His carefully prepared and admirably written paper presented to this body at the present meeting I should like to dscuss, but I perceive that it has been anticipated and effectually disposed of by Paul the Apostle in his first epistle to the Corinthians. For the convenience of those members who have not access to a reference library, I shall quote a few verses from the twelfth chapter:

"For the body is not one member, but many.

"If the whole body were an eye where were the hearing?

"If the whole were hearing where were the smelling?

"But now hath God set the members every one of them in the body as it hath pleased Him.

"And if they were all one member where were the body?

"But now are they many members yet but one body.

"And the hand cannot say unto the eyes I have no need of thee, nor again the feet to the head I have no need of you.

"Nay, much more those members of the body which seem to be more feeble are necessary;

"And those members of the body which we think to be less honourable upon these we bestow more abundant honour; and our uncomely parts have more abundant comeliness.

"For our comely parts have no need; but God hath tempered the body together, having given more abundant honour to that part which lacked.

"That there should be no schism in the body; but that the members should have the same care one for another.

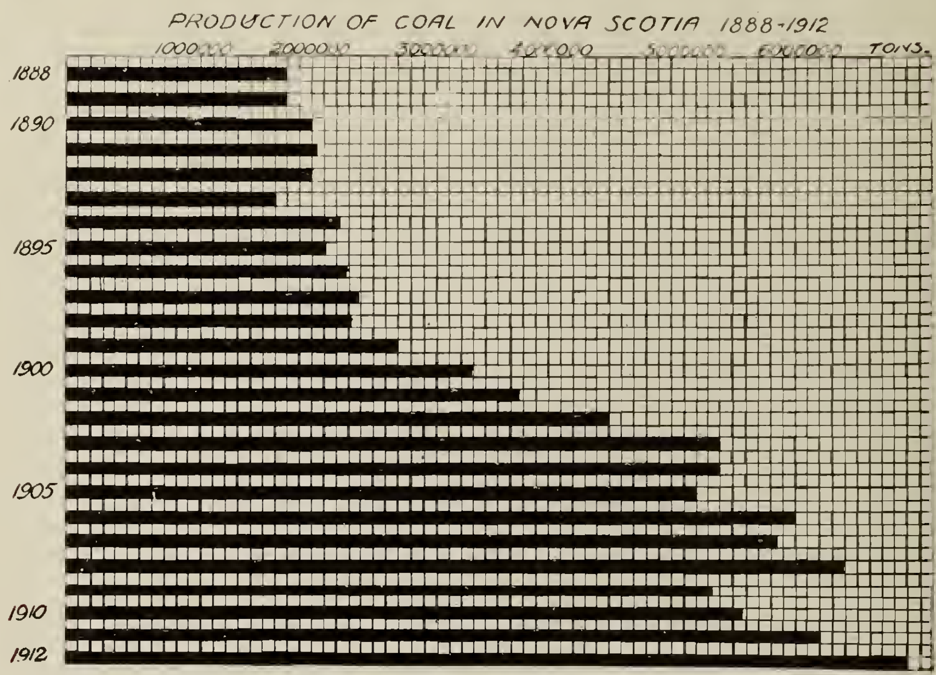
"And whether one member suffer all the members suffer with it; or one member be honoured, all the members rejoice with it."

# NOTES FROM THE ANNUAL REPORT OF THE DEPARTMENT OF MINES OF NOVA SCOTIA.

**Nova Scotia Mineral Production.**

Year ended September 30th, 1912.

| Mineral. | Quantity. 1911. | Quantity. 1912. |
|---|---|---|
| Coal raised (gross tons) ........ | 6.208,444 | 6.802.997 |
| *Iron ore (net tons) ........... | 53.595 | none |
| Pig iron made (net tons) ...... | 397,614 | 411.388 |
| Steel ingots made (net tons) ... | 438,922 | 561.392 |
| Limestone quarried (net tons) .. | 525.286 | 473,067 |
| Coke made (net tons) ......... | 545.619 | 603.372 |
| Gypsum quaried (net tons) ... | 333.358 | 280.000 |
| Building stones quarried (net tons) .................. | 11.226 | 11,644 |
| Bricks made (number) ........ | 23.273.700 | 22,348,486 |
| Drain pipe and tile made (feet). | 1.431.761 | 984,922 |
| Grindstones quarried (net tons). | 380 | 400 |
| Gold bearing ore mined (net tons) | 18.320 | 15.868 |
| Gold produeed (ounces) ....... | 8,389 | 4.948 |
| Manganese ore (net tons) ..... | 150 | 233 |
| Antimony concentrates (net tons) | 191 | none |
| Moulding sand (net tons) ...... | 380 | 1,190 |
| Tungsten concentrates (net tons) | none | 14 |
| Sulphate of ammonia (gross tons) | 3.971 | 5.213 |
| Barytes .................... | | 974 |



## Coal Trade.

The returns of eoal sold during the year 1912 show, compared with the returns for 1911, as follows:

| | 1911. | 1912. |
|---|---|---|
| Nova Scotia ............... | 2,108,665¾ | 2.295,363 |
| New Brunswick ........... | 541,591 | 653,938¾ |
| Newfoundland ........... | 184,195¼ | 200,642 |
| Prince Edward Island ...... | 80.637 | 92,302¼ |
| Quebec.................. | 2,067,831½ | 2,159,005 |
| United States ............. | 332,301 | 412,531 |
| St. Pierre ................ | 9,024½ | 9,406¾ |
| Other countries ........... | 1,992 | 91,825 |
| Bunker .................. | 204,681 | 236,733¾ |
| Time chartered boats ....... | 25,545 | 25,867½ |
| | 5,556,464 | 6,177,615 |

*Iron ore imported 1910-1911, 853,904; 1911-12, 880,409 net tons.

## Cape Breton County.

The produetion for the year 1912 was 5,197,601, as compared with 4,736,026 for the year 1911. The largest producers were the Dominion Coal Co., Ltd., with an output of 4,332,320, and the Nova Seotia Steel & Coal Co., Ltd., with an output of 821,165 tons.

The reports of Mr. Neil A. Nieholson and Mr. John J. MeNeil, Deputy Inspector for the districts of Cape Breton, give (pages 17 and 52) for their district, detailed information eoneerning the collieries and their operation.

## Pictou County.

The production for the year 1912 was 682,883 tons, as compared with 727,944 tons for the year 1911.

The principal produeer was the Acadia Coal Co., Ltd., with an output of 439,476 tons.

The report of Mr. Thomas Blackwood, Deputy Inspector, for the pictou district, gives (page 94) for his district, detailed information concerning the collieries and their operation.

### Cumberland County.

The production for the year 1912 was 632,809 tons, as compared with 411,695 tons for 1911.

The reports of Mr. A. V. Cameron and Mr. E. B. Paul, deputy inspectors, give (page 148) detailed information concerning the collieries and their operation in the Cumberland district.

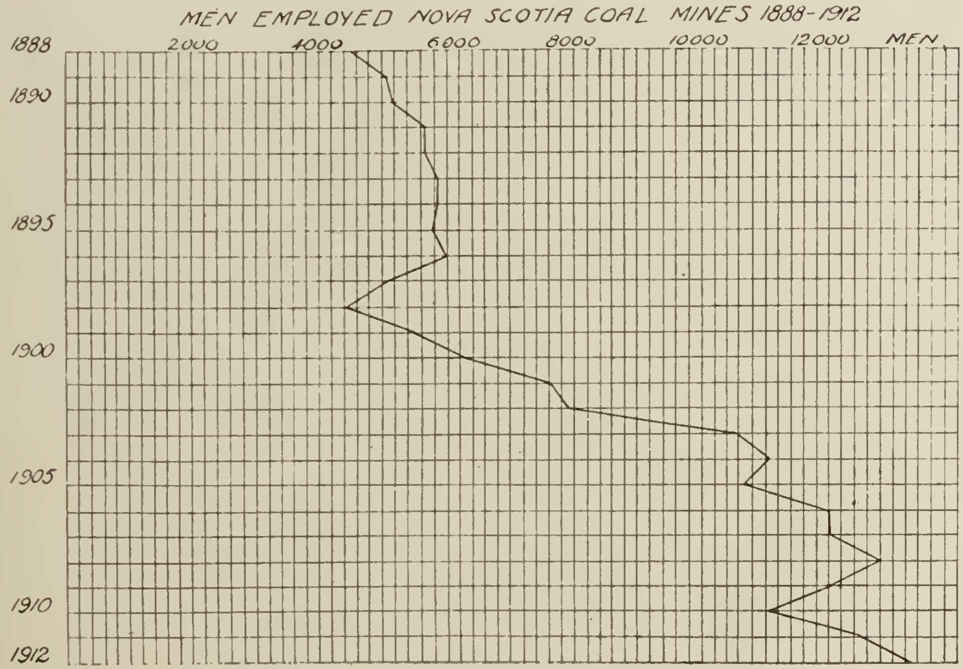
### Inverness County.

The production for the year 1912 was 289,704¼ tons, as compared with 332,779 tons for 1911.

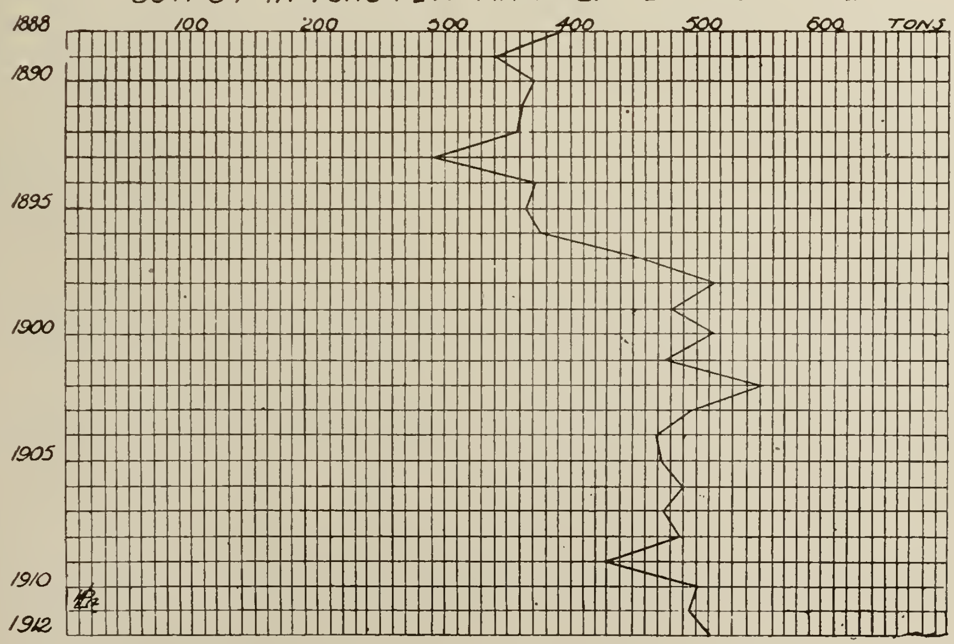
The whole production was by the Inverness Railway and Coal Company.

The report of Mr. W. F. Davis, deputy inspector for the district of Inverness, gives (page 135) detailed information concerning the Inverness Railway and Coal Company's Colliery and its operation.

MEN EMPLOYED NOVA SCOTIA COAL MINES 1888-1912



OUTPUT IN TONS PER MAN PER YEAR 1888 - 1912



### METALLIFEROUS MINES.

The minerals other than coal, mined in the Province during the year, were gold, manganese, tungsten and barytes.

The report covering the operations in connection with these minerals by Mr. H. B. Pickings, deputy inspector of mines, is contained in the following pages.

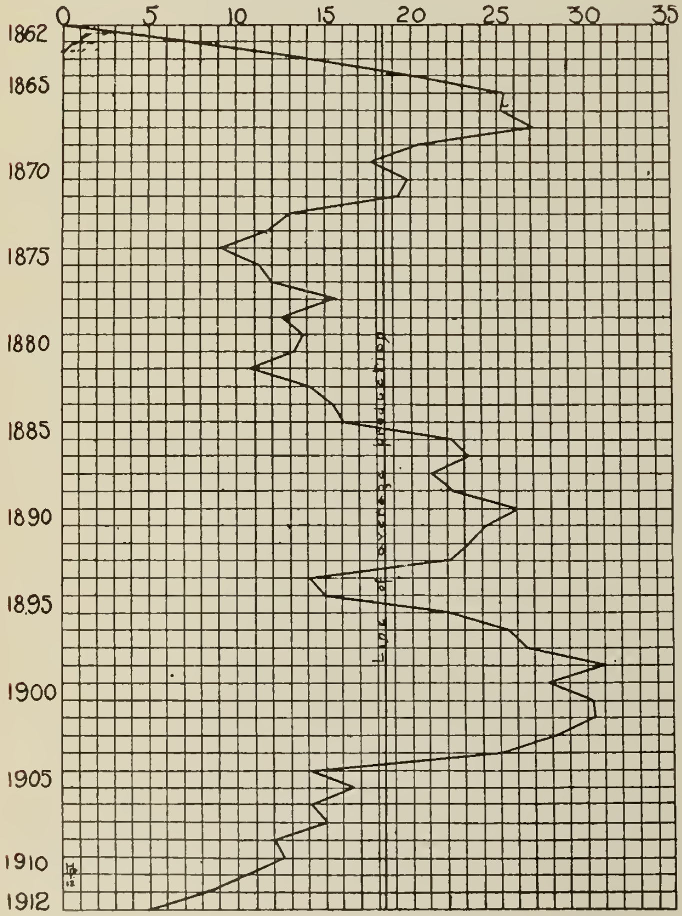
### Gold.

The production of gold was 4,949 ounces recovered from 15,862 tons of gold bearing rocks mined and crushed. This production having a value (at $19.00 an ounce) of $94,031.00 equaling an average recovery of $5.99 a ton crushed.

Compared with the production of the year 1911 this year's production shows three decreases as follows: 2,452 less tons crushed; 3,441 less ounces of gold recovered, and $2.71 less in the value of the average yield a ton.

The gold production is lowest since gold mining was established as an industry in the province; and it is almost needless to say is most disappointing. It is, however, but justice to the industry to say that it does not fairly represent the extent of the operations carried on, as at several of the districts the principal efforts of the operators were directed to mine development and prospecting rather than to immediate recovery of gold. At Tangier, the Dominion Leasing Co., had at the close of the year commenced only to recover from the setback caused by the destruction by fire of their charthouse and power buildings. At Lake Catcha the operations of the Petpeswick Mining Company were almost wholly of a prospecting and ore-development

YEARLY YIELD OF GOLD
1862 to 1912



nature, and at Caribou and Fifteen-Mile brook, a great percentage of work done was that the miner terms "dead work." At Shier's Point and Goldenville the surface equipments have received much more attention than the underground workings.

The properties on which operations were carried on were the following:

Byron Bower, Carleton.
Tonquoy, M. J. O'Brien and tributors, Caribou.
Stillwater Mining Co., Moose River.
Switzer Mining Co., Fifteen-Mile Brook.
Uniac Mines & Power Co., Gold River.
W. McBrennan and tributors, Oldham.
M. J. O'Brien et al, Renfrew.
New England Mining Co., Stormont.
Sydney Gold Mining Co., Stormont.
Seal Harbour Mining Co., Stormont
Boston and Goldenville Mining Co., Shier's Point.
Goldenville Mining Co., Sherbrooke.
Dominion Leasing Co., Tangier.
Gladwin Gold Mining Co., Beaver Dam.
S. R. Giffin & Sons, Stormont.
Petpeswick Mining Co., Lake Catcha.

I regret to have to report one fatal accident which occurred at the Dominion Leasing Company's mine at Tangier. Particulars of this accident will be found in the detailed report on this mine.

Generally speaking, the underground workings are in good condition and the requirements of the "Regulations of Metalliferous Mines" have been generally complied with. Some complaints have been made by mine managers that these regulations in not making more distinction between "mining operations" as permanent work and "prospecting operations" as temporary work, impose hardships that are detrimental to the expansion of the industry, and it would appear that there is some justice in their complaint and that this is a matter that should receive consideration, affecting as it does not only gold mining, but all mining and prospecting for minerals other than coal. Another feature of the Act that is more or less freely criticized is the manner of leasing and holding gold areas for speculation purposes, rather than for mining operations. There is no doubt that this feature of the Act as it stands to-day is having the effect of causing much property to remain unoperated that otherwise would receive attention. I realize that legislation, to successfully cope with these matters, without being productive of new features possibly just as objectionable as the features to be overcome, is a difficult problem, but at the same time the opinion is expressed that it is possible to pass legislation that will do away, to a great extent, at least, with this objectionable feature, and that such legislation would have an immediate and lasting effect for the expansion of the industry.

### Iron.

Since the closing down of the mines, at Torbrook, of the Canada Iron Corporation in 1911, no iron ore has been mined in the province. The Canada Iron Corporation have concentrated ore from their stock pile, however, and shipped several cargoes. Prices have improved, and the above-mentioned company is now commencing operations preparatory to reopening their mine.

Near Glencoe in Inverness County considerable prospecting has been engaged in on a very promising body of iron ore, taken up by John S. Hart.

### Antimony.

At West Gore, the West Gore Antimony Co., retimbered a part of their main shaft, but as yet no ore has been mined, and the mill has remained idle during the year.

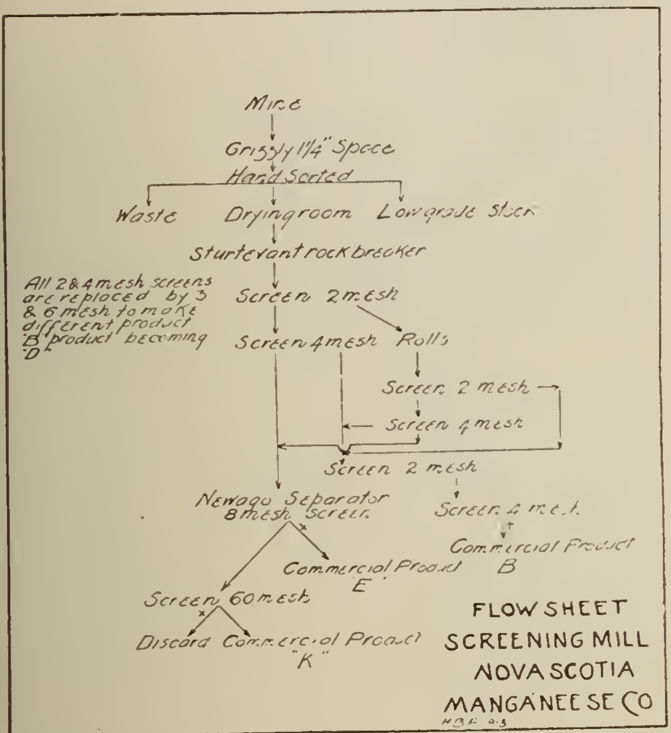
### Manganese.

The Nova Scotia Manganese Company at New Ross, continued development work and raised 233 tons of ore recovered from this development work. The new road to tide water by way of Benjamin's Mills, is nearing completion, and stoping of ore is soon to be commenced.

No other properties were operated during the year in connection with the mining of this mineral.

### Tungsten.

The first shipment of Tungsten-bearing mineral from Nova Scotia, namely, 14 tons of scheelite concentrates containing 72 per cent. tungsten acid, were shipped during the past year from the Scheelite Mines, Limited, Scheelite, Moose River. The concentrating mill con-



structed in 1911 was operated, producing a very high-grade concentrate. Development work at the mines of this company was continued and prospecting for tungsten-bearing minerals has been engaged in at a number of places in the province.

### Barytes.

A total of 974 tons of barytes was mined by the Barytes, Limited, at Scottsville, Inverness Co. This company have put their new mill in operation, and during the year have shipped their manufactured product as far West as Winnipeg.

### Oil.

The Maritime Oil and Gas Co., Limited, have continued their oil-well boring operations at North Lake Ainslie.

To date, five test-holes have been put down to various depths as follows:—

| | Feet. |
|---|---|
| No. 1 hole | 800 |
| No. 2 " | 1612 |
| No. 3 " | 1120 |
| No. 4 " | 1100 |
| No. 5 " | 870 |

No. 6 hole is about to be started

These holes are all located within a territory at North Lake Ainslie, of about one square mile in extent.

Oil sands and natural gas have been encountered in all holes, and it is stated that at No. 2 hole over 215 feet of oil sands were drilled through, two of the beds encountered being 75 feet and 130 feet in thickness, respectively. This No. 2 hole has been cased and capped, ready for shooting, which is being delayed until another hole has been put down to the 75 feet bed. The drilling is being done with a standard oil drilling equipment as supplied by the Oil Wells Supply Company. The derrick used is 75 feet high.

The size of No. 1 hole when commenced was 10 inches in diameter, but this was found to be too small on account of the frequent caves, and the size of the other holes was increased, the last holes being 18 inch. This allows of casing and reducing six times, or until the hole has been reduced to 5 3-18 inch diameter.

The last year's work has been on the drilling of No. 5 hole. Progress all through has been greatly retarded on account of the many crevices and beds of quicksands met. No. 6 hole is to be located nearer the lake, and it is hoped will encounter a better drilling formation.

### Quarries.

The information in the report is from inspection and from official records.

The quarries are all in good condition, worked systematically and with due regard to safety. There are about 1,400 men employed, not regularly. The output for the year was, gypsum 280,000 tons; building stone 10,690 tons; limestone 473,067 tons; grindstone 400 tons; granite 954 tons.

One fatal accident was reported in the year: Reuben B. Smith, age 50 years, was killed at the Wentworth Gypsum Company's quarry near Windsor. He was caught under a dump car while oiling it. A verdict of accidental death was given by the jury of inquest.

Copies of the Act relating to quarries, and the necessary forms for making returns have been sent to all operators in the province; but it is difficult to get prompt returns.

The principal material quarried is gypsum (sulphate of lime).

Nova Scotia is rich in this mineral, generally of pure quality.

A glance at the geological map, readily shows that the coboniferous system in Nova Scotia, lies in the counties of Cumberland, Colchester, Hants, Pictou, Antigonish, Inverness, Victoria, Cape Breton and Richmond. The carboniferous series is the home of the gypsiferous deposits, and these counties contain immense deposits of gypsum.

In the territory lying between Minudie and Pugwash, there are large deposits, especially at Nappan River, and at Pugwash. In Hants County, it is quarried near Windsor, in the outcrop of an immense vein. It is quarried at Newport, Cheverie, Walton, and Noel, in the same county. In Pictou it is found in workable quantities on the East River. In Antigonish it is exposed, in one place on the coast, for a height of 200 feet. The bed of gypsum from which Plaster Cove, now Port Hastings, took its name, is of enormous thickness, two-thirds of which is anhydrite or hard gypsum.

Near the mouth of Mabou River, there is another immense deposit: a peculiarity about the gypsum in this vicinity is; that it crops alongside the coal, both being in the Lower Carboniferous. It appears again at Cheticamp, and is quarried and manufactured at Eastern Harbour, by the Great Northern Mining and Railway Company.

It lies in many places along the Margaree River, and at Lake Ainslie. It abounds at Big Harbour on the Bras d'Or Lake, and at St. Ann's, where the Victoria Gypsum, Mining and Manufacturing Company is working a large quarry. Another deposit is being worked in Victoria County, at Ottawa Brook, near the Intercolonial Railway.

At Lennox Passage, Isle Madame, in Richmond County, there is a large bed of exeellent quality. In Cape Breton County there are large deposits, but they have not been worked to any great extent.

The surfaces of all these beds of gypsum are marked by inverted cone-shaped cavities, known as plaster pits or kettle holes. In some deposits they are not exposed, save the tops, and gypsum may be traced by these, where there is no outcrop. These cavities are formed, some geologists say, by the solvent action of surface water penetrating the fissures of the gypsum. Other authorities contend that kettle holes are formed by escaping gases. The cavities are more contracted in the anhydrite.

The increase in the production of gypsum is about proportional to the increase in the manufacture of cement: this and the slow increase in the building trades and other purposes for which white gypsum is used, regulate the production. The quantity is, easily, far in excess of the demand for many years to come. The grey and blue varieties are used for cement and for agriculture, and are available for many years.

The output of gypsum in Canada in 1911 was 505.457 tons, valued at $978,863, half of which was produced in this province.

The following is an analysis of gypsum quarried at Eastern Harbour, Inverness County:—

| | % |
|---|---|
| Insoluble residue | .30 |
| Oxide of iron and Alumina | .10 |
| Calcium sulphate | 90.49 |
| Calcium carbonate | 2.01 |
| Magnesium Carbonate | .76 |
| Moisture | 5.70 |
| Undetermined | .64 |
| | 100. |

An analysis of Hants County gypsum shows the following:—

| | |
|---|---|
| Lime | 32.62 |
| Magnesia | tr. |
| Ferric oxide and alumina | .86 |
| Sulphuric Anhydrite | 46.08 |
| Water, loss on ignition | 20.30 |
| Insoluble mineral matter | .14 |
| Carbonic anhydride | tr. |
| | 100. |

Building stone is quarried near Pictou, and at Amherst and Wallace, grindstones are quarried on the west side of Merigomish Harbour, limestone is quarried at Ball's Creek, and at Leitche's Creek in Cape Breton County, dolomite at George's River, Cape Breton County, marble and limestone at Marble Mountain, Inverness County. The output of limestone, dolomite and marble is used in the furnaces of the steel works at Sydney and Sydney Mines.

# MOLYBDENITE DEPOSIT AT TURN BACK LAKE, QUEBEC

By R. O. SWEEZEY, B.Sc.

Molybdenite for some years was known to occur at Turn Back (Keewagama) Lake in Northern Quebec, but it was not until November, 1909, that the writer's attention was attracted by samples of this ore which were shown him by some Indians. A brief examination of the deposits showed their importance and a selection was at once made covering the best showing and 720 acres was staked.

At the present time these properties are most readily reached via Transcontinental Railway from Cochrane, Ont., 140 miles east to Davey Lake, Que., thence by overland road four miles south, thence by canoe a half day's travel to the properties on Indian Peninsula, Turn Back Lake.

To a large extent the surrounding country is covered by dense forest growth and by a heavy clay mantle. The rock formation is Keewatin. On Indian Peninsula the rocks are mostly coarse grained and pegmatite granites, which have intruded through the older schistose Keewatin. Later there were intrusions of large dykes of diabase. These softer Keewatin rocks have been worn down but the granite rocks reach boldly up to a height of about 300 feet above lake level. On the northern part of the peninsula some 30 to 40 quartz veins occupy fissures in the granite and have a bearing roughly northwest. On the two claims situated on the southern part of the peninsula there are about as many more of these quartz veins bearing the same direction.

These veins vary in width from a foot to over 10 feet, with the greater number over three feet wide. The quartz is clear, smokey, and rose tinted. The contact with the granite walls is clearly defined, the quartz breaking away readily.

Greenish white mica is usually present in the walls forming as it were a lubricant at the contacts.

Work has been carried on prospecting these properties during the past three summers with a force of ten to twenty men. Most of this prospecting work was executed on the 440 acres of the properties situated at the north end of the peninsula while the 280 acres on the southern part of the peninsula were only scratched along the lake shore where the outcroppings are more easily worked.

The length of vein matter uncovered and traced on the north claims aggregated over 16,000 feet. One of these veins was traced for 2,000 feet without a break, while indications leave no doubt as to its length being at least 2,600 feet. Several veins have been traced for over 500 feet in length.

The molybdenite occurs in these quartz veins usually associated with mica and in most cases concentrated at the walls of the veins and within a width of six inches or a foot on each wall, but within the quartz matter. In a few cases though the molybdenite has entered the granite walls to a depth of a few inches. Bismuthenite occurs in some of the veins associated with the molybdenite but usually it is found in isolated long needle-shaped crystals in the quartz and removed from the walls.

By rejecting the central part of the quartz veins there would be practically no loss of molybdenite. The richest veins of molybdenite ore bodies have been found on the eastern side of the north properties where the contact of granite and Keewatin schist is located. Along this contact which is traceable for over 1,500 feet on the properties there are three or four veins three to eight feet wide which have been broken here and there by the irregularity of the contact, but are traceable for lengths of 500 feet and over. One of these veins especially, which has been traced and uncovered for a length of 450 feet, seems to lose its identity as a true fissure vein and becomes a filling between the granite and schist following the irregularities of the contact. This quartz filling has been trenched across in a couple of places, and in one trench 15 feet deep where the quartz mass is eight feet wide an average sample selected with care throughout the whole mass in the walls of the pit, by Dr. T. L. Walker, of the University of Toronto, gave an assay of 6.4% molybdenite. Several other average samples were taken along this same ore body and gave assays of from 2.17 to 2.3 per cent. molybdenite. This vein has not been thoroughly explored, and only in one place has a depth of 15 feet been reached.

Owing to the tendency for molybdenite to weather and oxidize, all the veins appear lean on the surface, and especially on account of the concentration of ore at the contact walls it is necessary to get down some three or four feet in the veins in order to get below the effects of weathering and oxidization caused by the percolating of water or subsequent freezing in the seams at the contact between quartz and country rock.

In sampling in some fifteen different pits throughout the north claims with a view to ascertaining the average ore contents, Dr. Walker found the average assay of 1.92 $MoS^2$. This takes into account the whole of the vein matter, fully one-third of which would be rejected as barren and the other two-thirds of the quartz mass cobbed to one-half its bulk for crushing and concentrating.

There are portions of a few feet in the lengths of the veins which might be totally rejected in mining, but this would probably more than be made up for in other portions of the vein where the ore concentration would average about 6% of the vein matter. Several tons of ore have been taken out from these properties from time to time and concentration tests were made by Prof. J. C. Gwillim at the School of Mining, Kingston, by the Elmore Vacuum Process at Denver and by the Henry E. Wood Ore Treating Co., Denver. All of these tests were satisfactory though certain difficulties were met with. As a result it was found that a very successful and efficient concentration may be employed by a combination of parts of the three methods used in the tests.

The St. Maurice Syndicate of Quebec owns these molybdenite claims and has carried on the development and prospecting work on the properties. No attempt has been made to sink shafts to any depth beyond 20 to 25 feet, the main object being chiefly to prove continuity of surface extent of vein matter within an economically workable area.

The reports of their consulting engineers show that the results of the work carried on are very satisfactory and presuming a reasonable continuity in depth of the veins with the same percentages of ore as found on surface sampling these properties should certainly become very important producers of molybdenite.

# PERSONAL AND GENERAL

Dr. Milton L. Hersey, of Montreal, left last week on a visit to California.

Mr. John E. Hardman has returned to Montreal from an absence of nearly three months in Mexico, where he was engaged in examining tin properties.

Mr. M. E. Purcell, chairman of the Western Branch of the Canadian Mining Institute, and who represented the branch at the recent annual meeting of the Institute in Otawa, returns to Rossland this week.

Mr. H. P. De Pencier has accepted an appointment to engage in consulting work with Mr. W. Mein.

Mr. Charles A. Banks, a mining engineer from New Zealand, who in the latter part of 1912 took charge of Jewel gold-mine and stamp-mill, and did mining and milling for two or three months, has left the Boundary district, British Columbia, in which the property is for England. A local newspaper states that he has gone to confer with the directors of the Jewel Syndicate relative to the substitution of a more effective process for treating the slimes than that with which the mill is now provided.

Mr. T. Walter Beam, of Denver, Colorado, who had much to do with the purchase of the Nickel Plate group of mines and 40-stamp mill in Hedley camp, Similkameen district, B.C., by those who organized the Hedley Gold Mining Company, has again been spending a few weeks in British Columbia.

Mr. Hermann Bellinger, general manager of the Great Cobar, Limited, was in San Francisco in February on his way from New South Wales to England.

Mr. C. Victor Brennan, chief mining engineer for the Utah Consolidator Co., has returned to Bingham, Utah, after a honeymoon trip from British Columbia to Southern California and thence to Salt Lake City, Utah.

Mr. C. M. Campbell, superintendent of the Granby Consolidated Co.'s big copper mines in Boundary district, British Columbia, has returned to his headquarters at Phoenix, after a wedding trip that extended over several weeks.

Mr. Lorne A. Campbell, general manager of the West Kootenay Power and Light Co., who is member for Rossland constituency in the Legislature Assembly of British Columbia, recently gave the local parliament some interesting and instructive information relative to the mining industry of Rossland camp (which to date has produced metals to an aggregate gross value of between $55,000,000 and $60,000,000). Mr. Campbell took advantage of the opportunity afforded him, when participating in the debate on the Provincial Budget, to show that the future of Rossland's chief mines is as promising as the past has been prolific in good results.

Mr. Herbert Carmichael who, at the end of 1912 voluntarily retired from the position of Provincial Assayer in British Columbia after more than twenty years' efficient service in that office, left Victoria on March 2 for England, intending to be absent from the Province three or four months.

Mr. W. G. Clark, who last October was one of the victims of an accidental explosion in the low-level adit of the Payne mine, Slocan, B.C., the work of driving which he was superintending, has returned to Sandon after having been several months in Vancouver under surgical treatment. One of his eyes was saved, but he has lost the other.

Mr. C. L. Copp, manager for the Coronation Mines, Ltd., of Victoria, B.C., has returned to the company's mine on Cadwallader creek, Bridge river, Lilloet district, B.C., to continue development work, with the main object of opening a sufficient number of faces of ore in the Coronation mine to allow of an adequate supply being maintained to keep the 10-stamp mill running continuously crushing ore. The mill is to be started next summer. Large samples of quartz sent to the company's office in Victoria, stated to be fairly representative of the first-class ore available, look promising for yielding payable gold returns.

Mr. A. W. Davis, of the Consolidated Mining and Smelting Co.'s mining engineering staff, has taken charge at the company's No. 7 mine, in Boundary district, where ore-production has been resumed after several months of inactivity at this one of the company's several mines.

Mr. Geo. Watkin Evans, coal geologist and mining engineer, of Seattle, Washington, has disclaimed, through the medium of the Victoria Times, any association with a Mr. Grossman in the examination of the coal property of the British Columbia Anthracite Coal Co., Ltd., he having made an independent examination of, and confidential report on, that company's coal lands in northern Skeena. Like many "hot-air artists," Mr. Grossman seems to have made use of the name of Mr. Evans and Mr. G. S. Malloch, of the Geological Survey of Canada, without the knowledge or consent of those gentlemen. There must surely be lots of gas obtainable from some of the northern Skeena and Graham Island coals, if one may judge by the published allegations of several of those who claim to know all about them.

Mr. Colin Fraser, who spent several months examining mining properties in Ontario and British Columbia, arrived in London several weeks ago on his return from Canada.

Mr. J. A. Fraser, member for Cariboo district in the British Columbia Legislature, recently gave his fellow-members in the local House some valuable information about the enormous mineral resources of the large area of territory contained within the boundaries of the electoral district he represents. Now that railway transportation facilities are being provided, it is expected these resources, heretofore largely neglected by reason of their remoteness from transportation, will be utilized in steadily increasing degree.

Mr. Robert R. Hedley, of Vancouver, B.C., expects to spend the month of March on the Queen Charlotte islands, whence he went early in the month.

Mr. C. P. Hill, of Montreal, actively interested in coal-mining enterprises in Alberta and British Columbia, was out West in February.

Mr. Joseph G. S. Hudson, of the Explosives section of the Mines Branch, Canada Department of Mines, went to Naimo, Vancouver island, B. C., in February, to be present at an official inquiry into the circumstances connected with the utter destruction of the steamer Oscar by an explosion of a cargo of dynamite she was carrying. Incidentally, much damage was done to colliery headworks on Protection island, and to buildings in the city of Nanaimo, this having resulted in considerable loss to the respective owners.

Mr. J. F. Menzies, of Roslyn, general superintendent for the Northwestern Improvement Co., of Tacoma, Washington, probably the largest owner of coal-mines in that state, on the invitation of the Western Branch of the Canadian Mining Institute, kindly consented to attend the fourteenth general meeting, convened to be opened at Naimo, B. C., on March 4, and deliver an address on mine-rescue matters. Mr. Menzies has taken great interest in first-aid and mine-rescue training and is fully informed on these subjects.

Dr. E. B. Milward, F.G.S., has for a year or more been resident in West Kootenay district of British Columbia, where he has been giving attention to the occurrences of mineral in parts of that large mining area. For years he was connected with the Bewick-Moreing firm of mining engineers, and in their interests visited various parts of the British Empire and other countries.

# ECHOES FROM THE MEETING.

Messrs. F. H. Sexton, A. C. Ross, and C. L. Cantley were representative Nova Scotians present.

While some familiar faces fro mthe United States were missing, the meetings were graced by Dr. James Douglas, Mr. W. R. Ingalls, Dr. Heinrich Ries, Mr. R. V. Norris, Mr. G. M. Colvocoresses, and others.

No master of ceremonies ever excelled Colonel J. J. Penhale. His mirthful dignity, his calm resourcefulness, his unbending tyranny, make him a marked man.

Past President Geo. R. Smith was called hastily away on business.

Mr. Neil Macdonald was among the missing. Both the applause and the Cobalt contingent suffered from his absence.

The deadly drops dealt out behind the stage-bar had such immediate effect as to endanger the dramatic unities.

Barring the fact that he called us the Canadian Mining Association, the Governor-General made no lapse. This is a constructive compliment to all concerned.

The officials of the Chateau Laurier were attentive, tolerant, and courteous.

The Cobalt contingent preserved all its traditions. Individually and collectively that contingent is a credit to its native lair. Would that all our mining camps were as loyal to the Institute!

Mr. Haultain's paper rang in pleasant change in the programme. The audience filled the room and overflowed into the corridor.

Major Leckie, brisk and cheerful as ever, took part in the proceedings throughout. Much missed was his side partner, Col. A. M. Hay.

Dr. J. A. Dresser is coming in to his own as a genuine humourist. He was one of the lights of the occasion.

Markedly in contrast were the speeches of the Premier and of Sir Wilfrid at the dinner. The former, impressive, thoughtful, dignified, and incisive, wields the intellectual sabre; the latter, elusive, rapid, graceful, chooses the rapier.

Sir James Grant was by no means least amongst the after-dinner speakers. He was listened to, as he always will be, with respect and sympathy.

The friends and adversaries—both included in the term "friends"—of Mr. Eugene Coste, sincerely regretteed his absence. With most of us Mr. Coste has become a habit.

As assured by Mr. G. C. Mackenzie, the members who failed to secure free trips on the Ottawa street cars, could obtain vouchers, and, later, refunds. The company will not go into liquidation.

**C. M. I. Group in front of Chateau Laurier, Ottawa.**

# SPECIAL CORRESPONDENCE

## ONTARIO.

**Cobalt, South Lorrain, Elk Lake and Gowganda.**—According to figures prepared by Mr. John McLeish of the Mines Department at Ottawa, the production for the province showed a falling off of 627,334 ounces in silver ounces. The production from the Cobalt camp showed a falling off of a million and a half ounces and a gain in value of a million and a half dollars. The increase in value for the province was about 12 per cent.

The Anglicization of the Cobalt camp continues. At a general meeting of the City of Cobalt mining company it was decided to accept the offer of an English syndicate for the sale of the property at 52½ cents a share. This would amount to about $750,000.

At the annual meeting of the Cobalt Lake mining company 90 per cent. of the stock was already in the hands of the English syndicate identified with the Cobalt Townsite mining company. The Chambers Ferland and the Silver Queen are in the hands of the Cobalt Aladdin and some tempting offers have been made to several companes with mines that have produced and are producing. That there will be more sales there is little doubt.

Development along the Cobalt Lake fault is attracting very general attention in the camp. The Cobalt Lake is finding rich shots of ore along the fault, but there is no continuity of ore body. So far development along the fault has revealed wide and sometimes rich ore shoots with intervening patches of barren ground. Development along the fault is, however, very inexpensive, one drill on the McKinley-Darragh making from 40 to 45 feet a week. At the north end of the lake the La Rose is now conducting some very interesting exploration on work with a view to opening the fault at lower levels. At one level the vein was cut showing over a foot of solid calcite, and now it will be intersected at a lower level. The Right of Way is also sinking to develop along it and on the Cobalt Lake several good and wide ore bodies have been opened up on it. The McKinley-Darragh has 1,200 feet of it on their property. They have lately been developing along the fault at the 250 foot level, where some rich ore has been struck. Beyond them again the Princess has struck four inches of cobalt in the fault at the 200 foot level. J. B. 2, which is all the Little Nipissing now has in the camp, has suddenly taken on value because the fault runs across it. Beyond it again the Hudson Bay is pushing a cross cut from the bottom of a 100 foot shaft in order to see what there is along the fault on their property. In a few months' time there will be some very valuable data on the subject.

The production at the McKinley-Darragh for the month of February was approximately the same as for January, namely, 180,000 ounces. This is lower than last year by reason of the fact that development is being retarded as much as possible at the Savage, where every ton of rock thrown on the dump will have to be re-handled at additional cost. The Savage addition to the McKinley mill will not be running till the end of April or May, when all Savage ore will pass over the aerial tramway to it. Intensive development on the McKinley is still producing good results. On vein 36 a shoot of ore 100 feet long has been opened up, and there is width of about twelve feet of milling ore. On the second swamp vein the top of an old stope is yielding unexpected good results, several rich stringers in a body of fair milling ore giving good tonnage. The McKinley-Darragh will pay its usual 10 per cent. quarterly on April 1, which will raise the record of that company to 156 per cent. and a gross total returned to shoreholders of $3,505,175.

Development on the old King Edward property at Cross Lake under the management of the York Ontario continues to be very interesting. When the Silver Cliff mine was closed down about two years ago it was concluded that silver in the diabase in this particular section of the camp was not worth mining. Now both the King Edward and the Silver Cliff have been reopened. The York Ontario, which obtained a lease on the old mine at very favourable terms, is mining the property most economically. Silver has been discovered, both in the wall rock and as vein matter in nearly every point where a drill has run, and there is already a good body of ore ready for the bumping tables now being installed in the old compressor house. As the City of Cobalt will undoubtedly make new arrangements for milling in the near future the little stamp mill will probably be available for the York Ontario in a few months. Everywhere in the mine it was discovered that a little development opened up ore. Whether this is worth mining is yet to be demonstrated, but there is certainly plenty of it. Very interesting, too, is the diamond drilling on the property. The drill has now been put down 600 feet below the adit level and the cores still show that the bottom of the diabase sill has not been reached. The management want to see what chances there is of picking up ore along the contact.

At the Silver Cliff Mr. W. H. Jeffery is in charge for Mr. Wigmore of Toronto, who has purchased the property on what appears to be easy terms. The old workings have already been pumped out and a gang set to work to clean up. No time will be lost in resuming development. On one of the old Prince properties adoining the King Edward some development is being attempted by a leasing syndicate. This property has never received much development. In 1906 the Mackenzie and Mann interests had an option on it for a big figure. They did some diamond drilling and sank a shaft, but discovered nothing which would justify the payment of the first big instalment of the purchase price. Since then it has lain idle. There is scarcely an old prospect in camp that is not been looked over and examined mainly, it is probable, for exploitation on the London market, though there is a demand for properties in the best parts of Coleman all over the country again.

Figures compiled by Mr. A. A. Cole show that there was a big increase in the tonnage of ore milled last year. The total tonnage rose from 329,462 in 1911 to 455,516 in 1912. Every mill in camp was busy with the exception of the Silver Cliff, and it is being reopened this spring. At the McKinley-Darragh, Beaver, Cobalt Lake and Casey additions are being made to existing plants which will raise the tonnage again for 1913. The Nipissing, Buffalo, Dominion, Reduction, Campbell and Deyells and the O'Brien are shipping concentrates, the other companies operating mills concentrates. There is now no mine in camp making regular shipments of low-grade ore and only three or four despatching it at all.

**Porcupine, Swastika and Larder Lake.**—So satisfactory has been the development of the ore body on the 260 foot level of the Golden Stairway ore body of the Dome that it has been definitely determined to make an addition of forty or sixty stamps to the present mill. Until further drifting has been done the determination for the smaller or the larger number of stamps will not be made. Whilst it has been generally understood that the forty stamps at the Dome would be duplicated this year, nothing definite had been stated.

On the first of March the Dome mill will be treating 450 tons per day. On this basis, with the addition of 40 stamps, the capacity will be raised to 900 tons per day, or, with 60 stamps, to 1,125 tons every 24 hours. At the present time all ore for the mill is coming from the glory holes on the Dome ore body. For the past nine months the mill has been running on a basis of 10,000 tons per month, and this is all coming from above the 100 foot level of this big ore body, where it is estimated there are yet between seven and eight years' reserves of ore, computing the capacity of the mill at its old level. As one drill can break down 75 tons per day into the shoots, the mining is necessarily the most economical.

The Dome is now running with electric power from Waiwaiten Falls. The coal bills has been for some time the feature in the cost which the management most desired to prune, and it will now be eliminated for all but heating purposes.

The new McIntyre mill is now running. The management was so anxious to get it started that they did not wait for the arrival of the agitating tanks, and they will be installed later. Ore will be fed to the mill from the 300 foot levels of No. 4 and No. 1 shaft, while the original mill will be kept going from the glory hole at the No. 1 shaft, where there is still much free milling ore at the upper levels. The capacity of the new plant is stated at 150 tons.

With the payment of the fifth dividend from the Hollinger goes a statement showing that the property is in a very healthy condition indeed. Production jumped in January from 1,373 tons, gross value $25.-

687, to 2,122 tons per week, gross value $59,313. Since the last report was issued the production has again been raised, so that it is now between $70,000 and $75,000 per week, or very considerably more than half as much again as for the whole of the gold production of Ontario for the year 1911.

General Manager Robbins reports "a steady improvement in values and tonnage will be noted. The relative decrease for the week ending January 28 was due to shutting down portions of the mill for much-needed repairs. Mr. Robbins also reports that development was, when the report was issued, along a lean streak in the main vein at the 300 foot level. This was anticipated, as the same conditions occur at all the upper levels.

Strike conditions in Porcupine are almost at an end. Most mines wanting to resume work have resumed and more will in a few days. The clearing of the air at Cobalt has relieved the stress all through Northern Ontario.

Operations at Larder Lake are largely confined to the Goldfields, Limited. A very valuable electric power plant has been erected at Raven Falls and is now running all the machinery at the mine. The power rights are capable of developing 10,000 horse power if it is ever required.

According to an official statement, "the ore body has been opened up for 130 feet in width and 600 in length and there are eight drills at work. Thirty stamps are dropping on ore.

# STATISTICS AND RETURNS

## DOMINION IRON AND STEEL. FEBRUARY OUTPUT.

The output at the plant of the Dominion Iron and Steel Co. for the month of February was as follows: Pig iron, 700; ingots, 22,560; blooms, 19,900; rails, 12,745; total shipments, 19,470. The February output of the Dominion Coal Co. was 336,000 tons.

## SCOTIA FEBRUARY OUTPUT.

For the past month Nova Scotia steel and coal outputs were as follows: Coal mined, 59,704 tons; pig iron made, 5,495; steel ingots, 4,828; ore mined, 79,535 tons; February being a short month.

## COBALT ORE SHIPMENTS.

Of the half million pounds of ore shipped out last week almost half was low grade. The Bailey Cobalt also sent out a car of ore running less than 500 ounces to the ton.

| | Ounces. | Value. |
|---|---|---|
| Nipissing | 921.98 | $54,587.97 |
| Buffalo | 28,338.00 | 17,000.00 |
| Kerr Lake | 1,500.00 | 900.00 |
| | 122,359.98 | $72,487.97 |

The shipments for the year to date are:

| Mine. | High. | Low. | Tons. |
|---|---|---|---|
| Townsite | 12 | | 426.68 |
| Crown Reserve | 1 | | 146.47 |
| McKinley-Darragh | 12 | | 436.36 |
| Peterson Lake | 1 | 2 | 115.96 |
| Wettlaufer | 1 | | 60.00 |

The shipments for the week ending March 8th in pounds are:

| Mine. | High. | Low. | Lbs. |
|---|---|---|---|
| Crown Reserve | 1 | | 60,162 |
| Coniagas | 3 | | 160,501 |
| Trethewey | 2 | | 83,600 |
| Bailey Cobalt | | 1 | 46,500 |
| Nipissing | | 3 | 211,005 |
| La Rose | 2 | | 35,776 |
| Cobalt Townsite | 2 | | 142,000 |
| | 10 | 4 | 539,544 |

The bullion shipments for the week were:

| | | | |
|---|---|---|---|
| Temiskaming | 5 | 1 | 168.85 |
| Beaver | 3 | | 78.10 |
| Kerr Lake | 3 | | 120.17 |
| Coniagas | 10 | | 362.86 |
| Trethewey | 6 | | 158.73 |
| Drummond | 5 | | 6,127.83 |
| Cobalt Lake | 4 | | 173.32 |
| Nipissing | | 9 | 306.29 |
| La Rose | 15 | | 538.86 |
| Hudson Bay | 4 | | 125.35 |
| Colonial | 1 | | 21.56 |
| Chambers-Ferland | 1 | 2 | 95.20 |
| O'Brien | 2 | | 87.41 |
| Dominion Reduction | 1 | | 85.80 |
| Bailey | | 1 | 23.25 |
| City of Cobalt | 1 | | 32.94 |
| Green-Meehan | 1 | | 12.96 |
| Casey Cobalt | 2 | | 59.32 |
| | 92 | 15 | 3,764.26 |

The bullion shipments to date are:

| | Ounces. | Value. |
|---|---|---|
| Nipissing | 878,000.20 | $484,626.22 |
| Buffalo | 258,867.00 | 162,100.00 |
| Dominion Reduction | 79,200.00 | 45,405.00 |
| O'Brien | 21,058.00 | 13,038.00 |
| Crown Reserve | 15,691.00 | 9,354.00 |
| Trethewey | 5,077.00 | 3,223.00 |
| Townsite | 6,770.00 | 4,209.00 |
| Casey Cobalt | 2,394.00 | 1,520.00 |
| Miscellaneous | 7,643.00 | 4,575.00 |
| Kerr Lake | 1,500.00 | 900.00 |
| | 1,276,600.00 | $686,935.22 |

## B. C. ORE SHIPMENTS.

### Week ending March 1st.

With last week's ore production the total in the Kootenay and Boundary district for the year to date reached the substantial figure of 407,232 tons, which is considerably above the average of 1912. Boundary ore output last week was 38,600 tons, which sent the total for the first nine weeks of 1913 flying past the 300,000 ton mark.

Receipts at the Consolidated Mining & Smelting Company's plant at Trail continued heavy and reached nearly 8,000 tons.

In the Nelson district the heaviest shipper was the H. B. at Deer Creek, in the Sheep Creek camp, which sent 326 tons to Trail smelter. The Queen Victoria shipped 300 tons to the British Columbia Copper Company's smelter at Greenwood.

Ore production for the week in the Kootenay and Boundary districts was 51,013 tons. Smelter receipts for the week were 45,013 tons and for the year to date 353,895 tons. Production in detail was:

### Granby Smelter Receipts.

Grand Forks, B.C.

## GENERAL MARKETS.

Coal, anthracite, \$5.50 to \$6.75.

Coal, bituminous, \$3.50 to \$4.50 for 1¼ inch lump.

### Coke.

March 10.—Connellsville coke (f.o.b. ovens).

Furnace coke, prompt, \$2.50 per ton.

Foundry coke, prompt, \$3.00 to \$3.25 per ton.

March 10.—Tin, Straits, 46.40 cents.

Copper, prime lake, 14.90 to 15.00 cents.

Electrolytic copper, 14.82½ to 14.92½ cents.

Copper wire, 16.00 to 16.25 cents.

Lead, 4.35 to 4.40 cents.

Spelter, 6.40 to 6.50 cents.

Sheet zinc (f.o.b. smelter), 8.25 cents.

Aluminium, 26.50 to 26.75 cents.

Nickel, 40.00 to 45.00 cents.

Platinum, ordinary, \$46.00 per ounce.

Platinum, hard, \$51.00 per ounce.

Bismuth, \$2.00 to \$2.25 per lb.

Quicksilver, \$40.00 per 75-lb. flask.

# PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assaye.- Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

## PUBLICATIONS

**The Geological Survey has published maps and reports dealing with a large part of Canada, with many local areas and special subjects.**

A catalogue of publications will be sent free to any applicant. A single copy of a map or report that is specially desired will be sent to a Canadian applicant free of cost and to others at a nominal price. The applicant should state definitely the Precise area concerning which information is desired, and it is often of assistance in filling an order for a map or report if he states the use for which it is required.

Most of the older reports are out of print, but they may usually be found in public libraries, libraries of the Canadian Mining Institute, etc.

### REPORTS RECENTLY ISSUED:

CANADA

)85. Descriptive Sketch of the Geology and Economic Minerals of Canada. Accompanied by a geological and mineral map of Canada, by G. A. Young and R. W. Brock.

1218. Summary Report of the Geological Survey for 1911.

NEW BRUNSWICK and NOVA SCOTIA

.113. Memoir No. 16. The Clay and Shale Deposits of Nova Scotia and portions of New Brunswick, by H. Ries and J. Keele.

QUEBEC

110. Memoir No. 4. Geological reconnaissance along the line of the National Transcontinental Railway in Western Quebec, by W. J. Wilson, accompanied by a map.

ONTARIO

1213 Memoir No. 28. The Geology of Steeprock Lake, Ontario, by Andrew C. Lawson. Notes on Fossils from Limestone of Steeprock Lake, Ontario, by Charles D. Walcott.

NORTH WEST PROVINCES

1204. Memoir No. 24. Preliminary Report on the Clay and Shale Deposits of the Western Provinces, by Heinrich Ries and Joseph Keele.

1211. Memoir No. 27. Report of the Commission appointed to investigate Turtle Mountain, Frank, Alberta, 1911.

BRITISH COLUMBIA

940. Report on Graham Island, B.C., by R. W. Ells. (Reprint.)

1121. Memoir No. 13. Southern Vancouver Island, by Charles H. Clapp.

1175. Memoir No. 21. The Geology and Ore Deposits of Phoenix, Boundary District, B.C., by O. E. LeRoy.

YUKON and NORTH WEST TERRITORIES

080. Report on a part of the North West Territories drained by the Winisk and Attawapiskat Rivers, by Wm. McInnes.

### MAPS RECENTLY ISSUED:

CANADA

)42. Mineral Map of Canada. Scale 100 miles to 1 inch.

NOVA SCOTIA

133. Map 13A. Kingsport sheet, Nova Scotia, No. 84. Scale 1 mile to 1 inch.

NEW BRUNSWICK

1181. Map 35A. Reconnaissance Map of Parts of Albert and Westmorland Counties, N.B. Geology and topography. Scale 1 mile to 1 inch.

QUEBEC

1112. Map 12A. Vicinity of the Tranco ntinental Railway, Abitibi District, Quebec. Scale 4 miles to 1 inch.

1178. Map 32A. Larder Lake and Opasatika Lake, Nipissing, Abitibi and Pontiac, Ontario and Quebec. Geological. Scale 2 miles to 1 inch.

ONTARIO

964. Geological map of portions of the districts of Algoma and Thunder Bay, Ontario. Scale 8 miles to 1 inch. Second edition.

ALBERTA

1132. Map No. 7A. Bighorn Coal Area, Alberta, by G. Malloch. Scale 2 miles to 1 inch.

BRITISH COLUMBIA

792. West Kootenay sheet, B.C. Geological. Scale 4 miles to 1 inch.

1167. Map 29A. Mother Lode and Sunset Mines, Deadwood, B.C., Topographical. Scale 400 feet to 1 inch.

1147. Map 19A. Lardeau, West Kootenay, B.C. Topographical scale 4 miles to 1 inch. Contour interval 500 feet.

1197. Map 47A. Law's Mining Camp near Tulameen, B.C. Geological. Scale 600 feet to 1 inch. Contour interval 50 feet.

1219. Map 54A. Nanaimo Coal Area, Vancouver Island, B.C. Scale 1½ miles to 1 inch. Contour interval 100 feet.

YUKON and NORTH WEST TERRITORIES

1089. Map 9A. Explored Routes on Parts of the Albany, Severn and Winisk Rivers. Scale 8 miles to 1 inch.

NOTE.—Maps published within the last two years may be had, printed on linen, for field use. A charge of 10 cents is made for maps on linen.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon. Letters and samples that are of a Departmental nature, addressed to the Director, may be mailed O.H.M.S. free of postage.

*Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.*

## For Mine Buildings

## Use Amatite ROOFING

IT'S the one ready roofing that is not affected in the slightest by coal smoke or acid fumes. It is made of the same waterproofing materials as are used in Barrett Specification Roofs which are so popular on railroad roundhouses, where the coal smoke and condensing steam cause even more severe exposure than on mine buildings.

Amatite Roofs can be laid without skilled labor, and once laid they require no painting or similar attention.

The wearing surface is practically a pitch concrete and naturally immune from rain, snow, sun or frost.

Amatite is sold in handy rolls. Nails and liquid cement supplied free.

*Send for free sample and booklet to our nearest office.*

## PYRITES IN CANADA

The chief advertisements that the mineral industries of Canada have received have been derived from the exploitation of rich gold and silver deposits. While both Canadian asbestos and Canadian nickel occupy unique positions, yet neither has been the source of very much popular excitement.

It is not desirable that any branch of the mining industry in Canada should have to live down a period of foolish flotations and of disproportionate expansion. For many years the mining of iron pyrites has been going on quietly in Canada. The world's production of iron pyrites is about 2,000,000 tons. Canada's production is, roughly, 100,000 tons per year. In the United States not more than 300,000 long tons are produced. The United States, however, imports practically three-quarters of a million tons from Spain, and is, also, the chief market for the Canadian mineral. For instance, one-third of the pyrites produced in Canada is shipped to the United States.

Within easy reach of the Canadian producer there are at least twenty large firms that are posisble purchasers of the Canadian product. In Canada itself there are five corporations manufacturing sulphuric acid. The market for acid is growing at a rate far greater than is the mining of iron pyrites.

The whole situation as regards Canada has been carefully investigated and fully reported upon in the latest monograph of the Mines Branch, Department of Mines, Ottawa. Dr. Alfred W. G. Wilson, Chief of the Metal Mines Division of the Branch, is the author of that monograph. It is entitled "Pyrites in Canada, Its Occurrence, Exploitation, Dressing and Uses." It is a well-printed, carefully illustrated volume of more than 200 pages.

Dr. Wilson approaches his subject after he has, evidently, been fully seized of its commercial meaning. The uses of sulphuric acid are numerous. The reduction of silver ores and the refining of petroleum are two of the largest channels. Both are of primary importance. Either could form the basis of a substantial iron pyrites enterprise, where the pyrites was being used for the production of sulphuric acid.

But, more important than either of these two uses are the possibilities held out by the paper manufacturing trade. In Europe the pulp mills that use the sulphite process use also iron pyrites as the source of their sulphur. This is not the case in Canada. Imported crude sulphur is used here. Yet it is commercially feasible, and most probably it would be commercially profitable to use pyrites in lieu of sulphur. Not only would this save all the complications of international carriage, but it would also make it possible for each manufacturer of pulp to secure and control his own supply of sulphur. Since Canada is becoming the largest supplier of pulp, the importance of her iron pyrites bodies is obvious.

## GOVERNMENT CORE DRILLING IN NOVA SCOTIA

Encouragement vouchsafed to miners by governments takes various forms. Not the least interesting is that of assisting the prospector in drilling his property. In this direction the Government of Nova Scotia has been particularly active.

The Nova Scotia Department of Mines operates seven prospecting drills of the following general description: Two diamond drills actuated by steam, making cores of two and one and one-tenth inches diameter respectively; two hand diamond drills yielding cores of the smaller diameter mentioned; two steam calyx drills making a six-inch core, and one smaller calyx drill.

Upon the filing of a small bond and of a certified cheque for $250, any available drill is placed at the disposal of the applicant. The drill is then sent to the desired place and is operated under the direction of a person responsible to the Department. The location of the holes is left to the discretion of the applicant; all other matters are controlled by the Department employee.

All expenses, including shipment from and to the place of storing, are charged to the applicant, and, in no wise does the Department hold itself responsible for the manner in which drilling is performed. However, the applicant is given every reasonable consideration. He can make formal complaint at any time and can be sure of a hearing. Copies of the drilling log are filed at the Commissioner's office and similar copies are given to the applicant.

In the year ending September 31st, 1912, 77 holes were bored, at total footage of 10,826 feet. The cost per foot ranged from very low figures up to $2.46 per foot. In a future issue we shall analyze these costs. Meanwhile it may be pointed out that this kind of assistance to the prospector and miner is practical and sane.

## THE ALBERTAN MINES BILL

In the course of the debate on the Mines Bill, now under discussion by the legislative body of Alberta, Mr. J. L. Cote, the member for Athabasca, made a strong plea for the establishment of a Provincial Bureau of Mines, with headquarters at Edmonton. Such a step, while commendable from every standpoint, may meet with objection on the ore score that the Dominion Government, having reserved the rights in the natural resources of the Province, the latter derives no direct revenue from its mines. Mr. Cote affirms, however, that the Province is entitled to the royalties on all coal mined under "road allowances," and this, he stated, would represent an annual revenue of not less than $100,000—a sum quite sufficient to maintain an efficient Provincial Bureau of Mines. Whether or not this contention is correct, it would still seem that any reasonable expenditure by the Province to establish and support such a department, would be thoroughly justified. In Alberta, agriculture is, of course, the principal industry, the total value of the production last year having been $38,400,000. Mining, however, comes second. The value of the coal production alone in 1912 was approximately $8,000,000. The production of cement represented at least $1,000,000, while there was a considerable production of lime, of brick and other clay products. These industries are developing at a very rapid rate; while in the utilization of non-metallic substances, at present disregarded, there are immense possibilities. For information respecting its mineral resources the Province is at present dependent entirely on the reports of the Dominion Department of Mines. Such information is naturally limited. A Provincial Bureau could render a far more efficient service in this respect; and could, and undoubtedly would, do much to stimulate industry in new directions by indicating opportunities of which advantage has not yet been taken. It is meanwhile certain that the Western Provinces of Alberta and Saskatchewan will be ceded the control of their natural resources in the near future. The immediate establishment of an Albertan Bureau of Mines would merely anticipate, therefore, a need that sooner or later will have to be provided; but by organizing a department now it would be in a better position to meet the calls on it that changed conditions would create.

## THE LABOUR QUESTION IN PORCUPINE

The somewhat complicated circumstances surrounding the labour situation in Porcupine call for a few words of explanation.

Some time ago a Mine Managers' Association was formed in the Pearl Lake section of Porcupine. To this Association the Hollinger Gold Mines, Limited, did not belong. Among the first steps taken by the Association was the reduction of the wages of workmen. A Board of Conciliation was asked for and obtained. The Board was convened. The result of its deliberations was substantially to uphold the rates set by the managers. This decision was rejected by the men.

The Hollinger management, which was not in any way represented in the Association, and which, consequently, had no voice on the matter, quite unexpectedly became the storm centre. On November 15th, 1912, a number of men, not employees of the Hollinger, came on the property at change of shift with the object of forcing the Hollinger miners to strike. In this they were successful. In one day the working force of the mine was reduced from 478 to 118. The point to be remembered here is that the Hollinger management had absolutely no warning.

It had been maintained by the management that the men would be willing to continue work at current wages were adequate police protection provided. This, after the opening of the strike, proved to be the case. Under a guard supplied by the Provincial Police, work was rapidly resumed at the mine and little difficulty was experienced in obtaining men. Meanwhile, informations were laid against several of the agitators. Three cases were brought to trial. Two agitators, Cleary and Holowoskawe, were fined $500 each with the option of 90-day imprisonment, and a striker named Croft was fined $50 with an option of 60 days in jail. All three elected to go to prison. This occurred in January, 1913.

Notice of appeal was served by the defendants. which appeals will have been dealt with on March 26th. Meanwhile, however, the Dominion Department of Justice was petitioned by the miners to release the convicted men. Strange to relate, this request was promptly granted, and the men returned at once to Porcupine. We are credibly informed, further, that they immediately renewed the strike agitation.

Unless there be some occult reason for the action of the Department of Justice, we are convinced that nothing more derogatory to law and order could have been done. The offenders were given a fair trial. They were convicted. They deliberately chose imprisonment in lieu of paying their fines. It looks, therefore, very much as if the men had entire confidence in the leniency of the Department. Whether this be the case or not, it remains a fact that the whole machinery of justice in Porcupine has been made a laughing-stock.

If the so-called Lemieux Act, and it was under the provisions of this Act that proceedings were taken, is to be operative at all, it should be adhered to in letter and in spirit. If not, it should be wiped out.

Suppose, for example, that the managers were to hire "strong-arm" men to terrorize employees of companies that paid higher wages than did the Association. What would ensue can safely be left to the imagination. Yet the cases are quite parallel.

## THE HOLLINGER STATEMENT

Under date of February 25, 1913, the president and the general manager of Hollinger Gold Mines, Limited, respectively, have issued statements covering the periods July 1st, 1912, to December 31st, 1912, and December 3rd, 1912, to February 11th, 1913.

Three dividends, each amounting to $90,000, were paid during 1912. The complete plant cost $606,223.54, and the sum of $302,639.19, which includes fire loss of $111,811.96, is charged to development. After disbursing $270,000 in dividends, writing off $106,225.54 from plant account, and $122,639.19 from development account, or $228,862.73 in all, the balance carried forward is $101,801.69. The net operating profits for the six months were $600,664.42. Two dividends have been declared since the end of the year. Taking into consideration the labour disturbances that hampered the management during November and December, this showing exceeds expectations.

Mr. P. A. Robbins' statement for the first six weeks of this year shows that 9,562 tons of ore yielded $240,-300, the average return per ton being $25.13. As the cost per ton is about $6 to $7, and as the capacity of the mill is now greater by 15 per cent., it will be seen that the present rate of production is ample for the continuation of monthly dividends.

## EDITORIAL NOTES

On page 95 of our issue of February 1st, the bald announcement was made that four Nissen stamps were discarded by the Northern Customs Concentrator Company of Cobalt. This, as it happens, was quite unjust to the manufacturers of the Nissen stamp. The fact is that the four Nissen stamps have seen much duty and were worn badly. It was ,therefore, more expedient to replace them with the ordinary stamps of which the company had a supply on hand. In no sense was the incident a reflection upon the Nissen stamp.

According to recently published returns by the London Mining Journal, the average yield of ore milled last year on the Rand was 28s. 6d., or slightly under $7 a ton. This is rather below the estimate of 29s. 5d. made by Mr. Hugh F. Marriott in a communication to the Engineer and Mining Journal in January last. But in any event it is agreed that the yield per ton in 1912 was nearly a shilling greater than during the preceding year. This was largely discounted, however, by an increase in costs of eight pence per ton, costs in 1911 having been eighteen shillings. The profit per ton represented nine shillings and eight pence, or a penny more than was realized in 1911.

Tragic as is the position of Julian Hawthorne and his two associates, it is inconceivable to think that they could have persevered in their promotions for so long without knowing exactly what they were doing. Warning after warning must have reached them before they were brought to trial. While the Canadian Mining Journal was probably the first publication to draw attention to the character of their flotation, it was by no means the only one. It is a sad commentary on the ethics of Canadian newspapers that not a few of our leading dailies assisted the promoters editorially.

One of the most interesting and instructive papers presented at the recent annual meeting of the Canadian Mining Institute in Ottawa, was that by Mr. H. W. Dubois, of Philadelphia, descriptive of recent developments in connection with hydraulic mining in the Cariboo district in British Columbia. Rather over a year ago Mr. Dubois, who is engineer for the Quesnelle Hydraulic Gold Mining Co., installed, despite the opposition of his board of directors, high carbon steel rolled plates as a lining for the sluiceways. These plates were half an inch thick and 58 inches square, the carbon content being from 0.80 to 1.20 per cent. Previous to the use of the steel plates the sluiceways had been lined with diorite blocks or boulders, which actually wore as much as eight inches in three weeks. After a whole season's operation the steel plates showed practically no wear. At first glance this difference would appear almost incredible, but the expalnation is found in the fact that the steel rapidly assumes an ice-like surface over which the material passes with a minimum of friction. The important effect of the installation was the reducton of operating costs to 2 cents per cubic yard of the material handled, or about one-half of the previous season's costs.

---

The advisability of increasing the field staff of the British Columbia Bureau of Mines was strongly urged in these columns some months ago. It is gratifying to uearn, therefore, that action in this direction has been taken, provsion having been made for placing two parties in the field this year in charge of competent assistants to the Provincial Mineralogist.

---

The discussion of the revision of the Banking Act promises to be more than a farce. The House of Commons Committee has called upon Mr. H. C. McLeod, former manager of the Bank of Nova Scotia, to give evidence. As Mr. McLeod has been the only outspoken advocate of the external audit, and as it is common knowledge that he dared to think for himself and to set at nought the Bankers Association, his evidence will mean something. The country is sick of the complacent platitudes of such admirable watch-dogs of the "interests" as Sir Edmund Walker. We make bold to suggest that representatives of the industries, particularly of the mining industry, be called as witnesses. Much light could be thrown upon the relation of banks and bankers to promotions, organizations and operation.

---

In the matter of profit distributions the mines of British Columbia made a better showing last year than for some time past; and there is now every promise that this record will be well maintained in the future. One of the several mines in this Province that paid handsome dividends to shareholders in 1912, was the Nickel Plate, at Hedley, in the Similkameen district, owned by the Hedley Gold Mining Company. According to the recently issued report of this company the ore treated last year averaged about $10.8, and yielded a net profit on the tonnage treated (70,455) of $385,880, of which $360,000, representing 30 per cent. on the capital, was distributed in dividends. With the showing now being made, there is every reason to expect a considerable revival of interest on the part of the investing public in British Columbia mining in the near future. At present the industry is on a sounder basis than at any previous time in its history.

---

### GEORGE MATTHEY, F.R.S.

The death is announced, at eighty-eight years of age, of Mr. George Matthey, F.R.S., on February 14th. Mr. Matthey was throughout a long commercial life, keenly interested in the advancement of scientific technology. The industrial separation, purification and general manipulation of platinum and its associated metals formed the field of Mr. Matthey's labours.

The international metric commission which met in 1870 in Paris had for its object the construction and verification of a new series of standards formed of platinum with 10 per cent. of iridium. After considerable work and expense in purifying the metals the alloy was produced; but on further examination by chemical analysis, it was found to be impure and, consequently, useless for the purpose for which it was required. Mr. Matthey was then invited by the French Minister of War to attack the problem. He quickly commenced the work of producing large quantities of platinum and iridium of extreme purity, and later cast the ingots of the alloy in Paris. These ingots were submitted to most critical tests and careful analysis, and found to be precisely of the nature and composition required.

Mr. Matthey was then persuaded to devote his skill to the construction of the bars having the special type of cross-section which had been decided upon. To this end he purchased a second-hand lathe and set one of his skilled workmen to fashion the bars of the required cross-section. The bars produced were fully satisfactory. Copies of them were supplied to all the larger countries of the world, and they now form the standards upon which the metric system rests. Mr. Matthey was appointed a member of the Legion of Honour. He took great interest in the manufacture of the salts of platinum used in the production of platinum photographic papers.—A. G. B.

---

## PERSONAL AND GENERAL

At the regular March meeting of the Council of the Canadian Mining Institute, held on March 4th. the following candidates for admission to membership were duly elected: Members—G. J. A. Buisson, Rossland, B.C.; Howard W. DuBois, Philadelphia, Pa.; Cadwallader Evans, Stellarton, N.S.; Thos. J. Flynn, Cobalt, Ont.; H. L. Forbes, Ottawa, Ont.; Gwynn G. Gibbins, Vancouver, B.C.; Chas. Spearman, Haileybury, Ont.; Bush Winning, Ottawa, Ont.; and Associates—Geo. C. Riley, Montreal, Que.

We congratulate Mr. C. V. Brennan, chief engineer of the Utah Con. Mining Company, of Bingham, Utah, on his recent marriage. Since his graduation from McGill four years ago, Mr. Brennan's career has been a brilliant one.

Mr. John McLellan, who is operating a small gold mine on one of the Queen Charlotte Islands, has returned from a visit to England.

Mr. Charles Fergie, of Montreal, left last week to inspect the collieries in Alberta for which he is consulting engineer. He will remain in the West for some weeks.

# CORRESPONDENCE

## "PERSONALS."

Home Life Building, Toronto, Ont.,
March 19th, 1913.

Editor, Canadian Mining Journal,
Toronto, Ontario.

Sir,—One cannot help but notice in reading the "Personals" in the various mining periodicals, the constant repetition in the names of engineers mentioned. This is undoubtedly a double hardship. It is unfair that a few engineers should bear the burden of sustaining this column by the constant and unwelcome use of their names, and it must be annoying to the editor to be compelled to repeat so often, and to lack in the supply of new matter for his readers. It occurs to me that if the busy or the modest engineer were furnished with adequate facilities for supplying this interesting information regarding himself and his whereabouts, it might largely act as a relief from this onerous burden.

With this in mind, I have drawn up an outline for a plan to furnish blanks to the various engineers,† which can be easily filled and posted to the journals. If these were properly elaborated they would reduce the labor of furnishing this information to a minimum, and would be a constant inducement to supply the various journals with this most important information.

I have simply attempted a meagre outline of a few of the paragraphs which should be included in this form. I leave it to your ingenuity and literary skill to enlarge, knowing that you are more capable of judging the necessities of the profession in this regard than I am. I suggest that if the subject were properly elaborated and copyrighted, it might be a permanent and large source of revenue.

Yours respectfully,
F. L. CURTIS.

## THE NEW MINISTER OF MINES.

Louis Coderre was born at St. Ours, Quebec, on the 1st of November, 1865. His parents, Alfred Coderre and Emma Fontaine, were both French-Canadians. The former was superintendent of the locks at St. Ours from 1888 to 1898.

Mr. Coderre was educated at the Primary School, St. Ours, St. Hyacinthe, and Montreal Colleges, and Laval University, Montreal. On the 1st of July, 1895, he was married to Marie Anne Sophie, daughter of Edouard Ste. Marie, of St. Henri, Montreal. He has two sons and two daughters.

Serving as a law clerk with Mr. Pagnuelo—who is now a justice in Montreal, and graduating in 1912, he became a partner in the firm of Primeau and Coderre. At the present time he is one of the firm of Coderre, Fortin and Coderre. In 1885, he was appointed City Solicitor for St. Henri, retaining the position until St. Henri was merged in Montreal.

Mr. Coderre was also legal adviser to Ville Emard from 1906 until it was annexed to Montreal. For five of the Montreal Bar, which is an elective office.

Although Mr. Coderre has always taken an active interest in political life, both legal and national, he did not seek any public office until June, 1908, when he ran against Mr. Decarie, in Hochelaga, for a seat in the Quebec House. He was defeated. Again in October of the same year he was candidate against Mr. Rivet, the Liberal candidate for the Dominion Parliament, but was defeated by a majority of only 185. In 1909, he sought office as a Controller of Montreal as an independent candidate, and was fifth in line for position, but as only four Controllers were to take seats he was again left on the outer circle of success. At the general election, September 21st, 1911, Mr. Coderre ran as the Conservative candidate against his old opponent, Mr. Rivet, and polled a majority of 1,373.

He is a Conservative in politics, a Roman Catholic in religion, and resided in Montreal.

# CANADIAN MINING INSTITUTE ANNUAL MEETING 1913.

## DR. A. E. BARLOW'S PRESIDENTIAL ADDRESS

(Continued from last issue.)

In 1846, owing to activity in prospecting and locating mineral lands on the southern shore of Lake Superior, and a favourable report by Mr. W. E. Logan, then (1842) newly appointed Provincial Geologist, some enterprising Canadians banded themselves together into two associations called "The Montreal Mining Company" and the "Upper Canada Mining Company." The former company having purchased, amongst others, what was then known as "The Bruce Mines Location," while the Upper Canada Company proceeded to develop the Wallace mine, the first place in Canada in which nickel had been discovered. The Montreal Mining Company continued operations from 1846 to 1865, when, from a variety of causes, the work proved unremunerative.

These early references to attempts to carry on mining operations, while instructive and interesting, have only an indirect bearing on the present status of the industry. The real inception of mining may be said to date from the completion of the constructon of the Canadian Pacific Railway in 1885. This rendered accessible a vast territory, much of which was underlaid by mineral bearing formations. Since then progress has been rapid and well sustained. It is thus interesting to note that in 1886, the first year for which complete statistics of the mineral production for the whole of Canada were collected, the value was reported as $10,-221,255, or about $2.23 per capita. In the succeeding ten years the value of the mineral production had increased over 100 per cent. representing the sum of $22,474,256, or $4.38 per capita in 1896. Chiefly as a result of gold mining activity in the Yukon, the increase in the next five years was nearly 200 per cent., the total value of mineral production in 1901 being $65,797,911, or $12.16 per capita. For the three years following there was a slight decrease from this amount, but in 1905 a very substantial increase was made the total value of the mineral production in this year being $69,525,170. From this year, the increase was steady and rapid until 1910, when the grand total registered was $106,823,623, averaging $14.93 per capita of population. In 1911 the mineral production showed a decrease of a little over 3 per cent. as compared with that of 1910, the total amount being valued at $103,220,994, or an average output per capita of $14.42. In 1912 there was again a very large increase, the total value amounting to about $133,127,489, or over $18 per capita.

Ontario has now taken her place as the premier province in mining of the Dominion, having passed British Columbia in 1909. The relative importance of the provinces as mineral producers for 1912 are as follows: Ontario contributed 38.33 per cent.; British Columbia, 22.20; Nova Scotia, 14.15; Quebec, 8.77; Alberta, 9.10; Northwest Territories, 4.42; while Manitoba, New Brunswick and Saskatchewan together only accounted for 3.03 per cent. of the total mineral output. As is probably well known to all of you present, Ontario is famous for its production of silver, nickel, copper, natural gas, cement and clay products; British Columbia for coal, gold, copper, silver and lead; Nova Scotia is chiefly noted for its coal and gypsum, and also in a minor degree, gold, stone and clay products. Asbestos accounts very largely for the Quebec mineral products, although graphite, cement, stone, copper and pyrites figure rather prominently, especially the three first mentioned products. Alberta's production is largely made up of values obtained from its coal, cement and clay products.

The mineral products of the Yukon are gold and coal, with some silver and copper. Manitoba produces gypsum, clay and stone products; Saskatchewan, coal and clays, while New Brunswick, which is the last on the list of provinces as a mineral producer, has chiefly gypsum, coal, iron and stone products.

The construction of the Canadian Pacific Railway was directly responsible for the discovery of the Sudbury nickel copper deposits, a mineral field which has, up to the present time, produced a total value of about 80 millions of dollars.

In 1877 asbestos was discovered in the serpentine hills of Thethford and Coleraine in Quebec, but it was not until 1884 that mining had made such progress that 1,141 tons were quarried, valued at $75,097. In 1912, the total production of asbestos was 111,175 tons, valued at $3,059,084, while the aggregate production to the end of the year had reached a value of nearly $35,-000,000. Quebec now contributes more than 75 per cent. of the world's total production of asbestos.

It was not until 1890 that claims were located on the gold-copper lodes which have made Rossland famous as a mining camp, and attracted attention to the whole interior of southern British Columbia. Since that time the production from this district alone has been more than $55,000,000.

The discoveries at Rossland stimulated prospecting over extensive areas in southern British Columbia, and in 1891 the ore bodies in the vicinity of Greenwood and Phoenix in the Boundary district were located. About the same time coal mining was becoming quite extensive in Alberta; while although the Klondike District of the Yukon was discovered in 1894, it did not become prominent until 1896. All of these discoveries and consequent active mining development work greatly stimulated interest in the mineral and the other natural resources of the country.

This period marked the real beginning of that considerable expansion which has since been so extraordinary. Cobalt was discovered in 1903, by the building of the Temiskaming and Northern Ontario Railway, and to the end of 1912 has produced nearly 32 million dollars worth of silver.

More interesting, however, than this brief narration of the marvellously rapid development of the mineral industry of Canada, are its future possibilities. None of us can realize the truly magnificent future of this vast Dominion, with an area greater than that of the United States, and almost equal to that of the whole of Europe. Two-thirds of this total area of Canada (3,729,665 square miles) is underlain by rock formations which, where adequately examined and prospected, have been found to contain exceedingly valuable, and in many cases, unique mineral deposits. In attempting to predict the future of the mineral industry of Canada, we have a few outstanding facts that should be of great assistance in this connection.

The Great Canadian Shield, or Protaxis, of North America, is a term in general use to designate the great V-shaped area of Pre-Cambrian rock which surrounds Hudson's Bay, extending from Labrador almost to the mouth of the Mackenzie River. The area of this great mass of very ancient crystalline rocks has been estimated at 2,000,000 square miles. Along the southern border it contains the nickel deposits of Sudbury, which contributes more than 70 per cent. of the world's supply of nickel, and which, in the near future owing to alterations and extensions undertaken, is likely to be more than doubled. At Cobalt are the world-famous silver deposits, whose development has given Canada third place in the world's silver producing countries. In the extension of these pre-Cambrian rocks into the United States, southwest of Lake Superior, are found the greatest iron mines in the world, with an estimated available ore of 1,950,000 tons, to which must be added 20.5% which had been consumed up to the close of 1910. In this area is situated also a copper camp which in the total of its production is the greatest in the United States. It is believed that similar copper bearing rocks, occupying a still greater area, and likely to be at least as richly productive, occur in the vicnty of Coronaton Gulf and Bathurst Inlet in the Arctic Ocean. A description of this mineral bearing area, from information then available, was given last year by one of our members, Mr. J. B. Tyrrell (Trans. Can. Min. Inst. Vol. xv., pp. 508-534. At this meeting Dr. James Douglas will give a detailed statement of the results of an exploration which has recently been conducted under his auspices. In these circumstances, therefore, it seems entirely reasonable to assume that these great northern areas contain vast deposits which will become available with the opening up of the country, and consequent furnishing of transportation facilities.

The immense possibilities of Canada from an agricultural standpoint are now a matter of general agreement, but the potentialities of mining in Canada are not so commonly known. It is the speaker's firm conviction that Canada's future greatness will depend more upon her mineral production than upon any other of her natural resources. Many of us have an abiding faith in the great lone northland, with its apparently barren and waste sketches of rock and water. The call for its successful development is as compelling as the missionaries' cry which came over from Macedonia. National greatness can only be achieved by obeying this mandate. An empire, half a continent, awaits the march of civilization. We may not falter or hold back.

---

# INTERNATIONAL GEOLOGICAL CONGRESS

**Meeting of Organization Committee, Ottawa, Tuesday, March 4th, 1913.**

The Organization Committee of the Twelfth International Geological Congress met at the Chateau Laurier, Ottawa, at 10.00 a.m., on Tuesday, March 4th, 1913.

Present—Dr. Adams, President, in the chair; R. W. Brock, General Secretary; W. S. Lecky, Secretary; and Messrs. M. B. Baker, A. E. Barlow, D. D. Cairnes, C. Camsell, A. A. Cole, A. P. Coleman, T. C. Denis, D. B. Dowling, J. A. Dresser, E. Dulieux, E. R. Faribault, W. F. Ferrier, W. L. Goodwin, Abbe R. C. Guimont, Eugene Haanel, E. Haycock, E. D. Ingall, E. M. Kindle, C. W. Knight, Lawrence M. Lambe, W. W. Leach, O. E. LeRoy, G. G. S. Lindsey, R. G. McConnell, J. McEvoy, W. McInnes, J. McLeish, W. G. Miller, W. A. Parks, J. B. Porter, W. Fleet Robertson, F. H. Sexton, J. B. Tyrrell, T. L. Walker, James White, A. B. Willmott, G. A. Young.

There were also present by invitation the following gentlement who are leaders of excursions: Messrs. J. W. Goldthwait, W. A. Johnston, Percy E. Raymond, John Stansfield.

Absent—Messrs. J. A. Allan, H. M. Ami, J. A. Bancroft, A. G. Burrows, Eugene Coste, R. D. Falconer, R. P. D. Graham, R. R. Hedley, R. A. A. Johnston, Joseph Keele, H. Mortimer-Lamb, G. F. Matthew, W. Nicol, J. T. Stirling, R. C. Wallace.

Mr. Frank B. Taylor, leader of one of the excursions had also been invited to attend, but was unable to do so owing to serious illness in his family. Dr. John M. Clarke, a leader, had also been invited but was unable to attend.

**Minutes of Meeting of December 2nd, 1910.**

The minutes of the inaugural meeting which took place on December 2nd, 1910 were read for the information of the Organization Committee:

Minutes of the preliminary general meeting held in Toronto on the second day of December, Nineteen Hundred and Ten to appoint the executive Committee of the Twelfth International Geological Congress, adopted as the minutes of the first executive meeting.

At the instance of the Director of the Geological Survey a meeting of Canadian geologists and Mining Engineers, was called for December 2nd, at 11 a.m., in Toronto to arrange for the Twelfth International Geological Congress, which is to be held in Canada.

There were present Dr. F. D. Adams, Mr. J. C. Murray, Mr. O. E. LeRoy, Mr. H. Mortimer-Lamb, Mr. J. A. Bancroft, Prof. E. Dulieux, Dr. T. L. Walker, Prof. M. B. Baker, Mr. J. B. Tyrrell, Mr. James McEvoy, Dr. W. G. Miller, Dr. W. A. Parks, Mr. J. McLeish, Dr. A. P. Coleman, Mr. R. G. McConnell, Mr. G. G. S. Lindsey, Mr. O. N. Scott, Mr. W. McNeill, Mr. W. S. Lecky, Mr. R. W. Brigstock, Mr. F. Loring, Mr. A. A. Cole, and Mr. R. W. Brock.

Dr Adam called the meeting to order and exand Mr. R. W. Brock, Secretary.

Dr. Adams caleld the meeting to order and explained the object. On motion of Dr. Miller, seconded by Dr. A. P. Coleman it was decided that the Congress should be held in Canada in 1913, this date being chosen on account of the British Association Meeting in Australia in 1914, and possibly the Winnipeg Exposition in Canada, also in 1914. The meeting then proceeded to elect officers for the Congress.

On motion of Dr. Miller, seconded by Dr. Coleman, Dr. Adams was elected President. Dr. Coleman moved and Mr. James McEvoy, seconded that Mr. R. W. Brock be elected Secretary, Dr. Miller and Mr. Tyrrell suggested that the offices of treasurer and secretary be combined. This was included in Dr. Coleman's motion and the motion thus amended was carried. On account of the great amount of work which would be necessary to make the meeting a success it was decided that a paid secretary or manager should be appointed to assist the secretary and Executive Committee.

The question of committees was then discussed, but it was decided that before these could be formed it would be necessary to decide upon the place of meeting.

Dr. Miller moved, seconded by Dr. Parks that the Congress be held in Toronto. This motion was carried.

In the discussion the point was brought out by Dr. Walker that local meetings might be held in the east and west as well as the main meeting at Toronto. This suggestion met with the approval of the meeting.

The discussion regarding committees was then resumed. In the course of the discussion it was was brought out that a large honorary committee, a large general committee, local committees, and an executive committee would be necessary. As a great deal would depend upon the careful selection of these committees it was decided to appoint a small executive committee who could spend some time and thought on the selection of the other committees. It was moved by Dr. Miller and seconded by Mr. LeRoy and carried, that the President, Secretary, Dr. Coleman and Mr. Tyrrell should be apointed a committee to recommend to this meeting names for an executive committee. It was moved by Dr. Miller, seconded by Mr. McEvoy that Dr. Coleman and Mr. Tyrrell be members of the executive committee. The committee nominated then retired and after fifteen minutes consultation recommended the following names as an executive committee: F. D. Adams, R. W. Brock, A. P. Coleman, J. B. Tyrrell, W. G. Miller, O. E. LeRoy, W. McInnes, T. Denis, W. A. Parks, G. G. S. Lindsey. The convener pointed out that the names were confined to persons living in the central part of the country on account of the necessity of the committee meeting at frequent intervals.

It was moved by Mr. Cole, seconded by Mr. McEvoy that the gentlemen recommended be appointed an executive committee of the Geological Congress with power to add to its members.—Carried.

Dr. Walker moved that the general committee, honorary committee and any other committees that might be found necessary be appointed by the Executive Committeee. This was seconded by Mr. M. B. Baker, and carried.

Dr. Walker moved, seconded by Dr. Miller that the Executive Committee be authorized to appoint vice-chairmen of committees who could act in case of the absence of the chairman.

An informal discussion then took place regarding the excursions which it was felt should be the main feature of the Congress in Canada. Various suggestions were made and it was decided to have the members consider this question carefully and send their suggestions to the Executive Committee who would go thoroughly into the matter.

On the question of major subjects for the Congress, it was felt that it might be advisable to get up a special memoir on coal similar to the one on the Iron Ores of the World prepared for the past Congress, as this subject would be supplementing the Iron Memoir.

The secretary stated that Dr. J. G. Anderson, secretary of the Eleventh Congress, had called attention to the fact that the Congress had accepted the proposal of Dr. Hobbs that an international inquiry on the subject "The Fracture System of the Earth's Crust" should be undertaken; that Congress in accepting this proposal expressed its opinion that the manner employed by the Swedish executive committee when undertaking inquiries on the iron resources and the post-glacial climate could serve as a model to the coming executive committee of Canada when organizing the proposed enterprise, and charged the named committee to arrange the matter with Dr. Hobbs.

The subjects for the Congress were left to the executive committee.

The meeting then adjourned to attend a lunch given by the Toronto Branch of the Canadian Mining Institute.

### Communications From Absentees.

The President read letters of regret from absentees.

### The General Objects and Work of the International Geological Congress.

The President briefly outlined the general objects and work of the International Geological Congress. As information on these subjects is contained in the Canadian Edition of the Second Circular which will be in the hands of members in a few days time, it is not repeated in these minutes. The President mentioned the splendid work which had been accomplished in the course of the different sessions, both in pure and applied geological science and which had resulted in such important publications as the Geological Map of Europe and the Monograph on the Iron Ore Resources of the World, the latter of which had been instrumental in starting new industries in various countries. In his closing words the President pointed out that the Twelfth or Canadian Session would accomplish its mission if it were successful in giving to the world in easily accessible form the results of geological research since the time of its last session and in particular he mentioned the publication which had been in preparation now for more than two years of the Coal Resources of the World. He hoped that the Canadian Geologists and particularly the younger members of the profession would gather great help and inspiration from meeting so many celebrated men from various countries.

### Arrangements for the Twelfth Session.

The General Secretary, Mr. R. W. Brock, outlined briefly the manner in which the Congress had been asked to hold its Twelfth Session in Canada and the general arrangements made up to the present time. The Congress had been invited by the Government of Canada, the invitation being officially transmitted through the foreign office and through the British Ambassador in Sweden. The Government invitation had been supported by the Province of Ontario conveyed personally at the Eleventh Session in Stocholm by Dr. Miller, the Provincial Geologist of Ontario and by the Canadian Mining Institute by the then President, Dr. Adams, who also on this occasion represented the Government of Canada and by the Royal Society of Canada.

The Government of Belgium had invited the Congress to hold its Twelfth Session in that country but the Canadian invitation, which was made for the second time, having previously been made in 1907 was accepted.

On December 2nd, 1910 an inaugural meeting was held in Toronto, the minutes of which were read today. It was called at the instance of the speaker acting for the Government as the Director of the Geological Survey. At it were present representatives of the Institutions who had invited the Congress to be present in Canada and as shown from the minutes of the meeting a small executive committee was appointed with instructions to appoint such other committees as might be required as and when they were required.

Committees dealing with the following subjects have been appointed: Coal Resources, Editorials, Excursions, Finance, Leaders of Discussions, Official Invitations, Patronage, Publications, Qualifications for Membership, Toronto Local, Transportation, and a committee to appoint an Assistant Secretary. Some of these committees have completed their work and have been dissolved but most of these are still active and consist of one or two members of the Executive Committee with in some cases other gentlemen but in each case they report direct to the Executive Committee which makes itself responsible for the financial arrangements. The Organization Committee had also been appointed and was meeting to-day for the first time.

With regard to the Monograph on the Coal Resources this will consist of 1,200 pages published in three volumes accompanied by an atlas of 70 maps. The work was well under way under the editorship of Messrs. William McInnes and D. B. Dowling and there was every reason to believe that it would be published in time and be a credit to the country.

The excursions would, no doubt, be the leading feature of the Congress and every effort is being made to make them attractive both to geologists and mining engineers. The itineraries of the excursions were contained in the second circular which was in the hands of the committee and it was therefore unnecessary to detail them. The guide books would consist of fifteen volumes comprising a total of more than 1,600 pages and a large number of maps. The manuscripts for the guide books were all completed with one exception and most of the material is in the hands of the printer and has reached the stage of galley proofs.

### Co-operation of the Mines Branch.

Dr. Eugene Haanel stated that as the excursions had already been planned and the routes made up he was a little at a loss to know in what way he could assist but he pointed out that there were on his staff men than whom there were none better qualified to serve as guides on the excursions, for example, there were on his staff one mining engineer who had made a study for the last three years of the copper resources of the Dominion and another who had made a specialty of mica and another who had made a study of iron ore deposits. Dr. Haanel assured the committee that he would give the Congress his hearty support and active assistance and would be glad for members of his staff to act as guides and to assist in the excursions. Dr. Haanel added that he thought that some of the monographs or summaries of the monographs published by the Mines Branch would be useful for distribution at the meeting and he stated that he had, in anticipation of the meeting, ordered a large number of Dr. Coleman's map of the nickel-copper deposits of the Sudbury district.

The President thanked Dr. Haanel very heartily for his promised assistance and pointed out that as this was a Geographical Congress we had not been able to make mining the principal object of any excursion but that in most of the excursions it was a very important incidental object and that as many visits to the mines and mineral deposits as possible would be made and that in connection with these the committee would take advantage of Dr. Haanel's kind offer and secure assistance from the members of his staff. Dr. Adams also pointed out that while the general routes and the leader of each excursion had been settled the list of guides had not been settled and also the routes and points to be visited were open to alterations. The Executive Committee would be glad to receive suggestions. Dr. Adams expressed a hope that the International Mining Congress which held its next meeting in 1915 in England could be induced to meet in Canada in 1920 when mining would be the principal object of the excursions.

### The Tenth Session in Mexico in 1906.

Dr. W. G. Miller gave a short address on the Tenth Session which was held in Mexico in 1906. He dwelt upon the generous support given by the Mexican Government in the way of money grants, free transportation on railways, great reduction in fares on steamers, etc. He was of the opinion that we could not hope to equal the brilliant social side of the Tenth Session and spoke feelingly of the hospitality of the Mexican people. The outstanding achievements had been:

(1). The guide books which had been pubilshed, giving exhaustive information on mining areas in Mexico.

(2). The Geological map of North America which had been so favourably commented upon by the technical papers.

### The Eleventh Session in Sweden in 1910.

Dr. A. P. Coleman gave an account of the Eleventh Session held at Stockholm, Sweden, in 1910. Dr. Coleman mentioned that while French was the official language of the Congress, English and German seemed to be predominant. The Swedes had made their preparations a long time ahead and their arrangements were carried out as planned and they had shown wonderful organizing ability which it would be hard to equal in Canada. The only criticism he had to make was on the belated publication of the "Compte-Rendu" which appeared more than two years after the Session. He thought that Canada ought to do better in this respect.

### Financial Requirements of the Twelfth Session.

Mr. G. G. S. Lindsey, chairman of the Finance Committee mentioned that the Executive Committee had been promised about fifty thousand dollars and that they expected to require about seventy-five thousand, all of which was needed for the general purposes of the Congress. Money necessary for local entertainments must, in his opinion, be raised locally.

The list of Honorary Councillors would be printed in the Canadian Edition of the Second Circular which had recently been destroyed by fire and he thought that the Honorary Councillors could be approached for financial support in the matter of local entertainments and local expenses.

Mr. Lindsey mentioned that the central part of the Twelfth Session would, in his opinion, be the excursions and he considered it to be the duty of the leaders to see that the social side of the excursions be properly conducted and that on a high standard.

### Duties of the Organization Committee.

The General Secretary read the following report enumerating the duties of the Organization Committee and this report was adopted without discussion.

"It has been the custom of previous geological congresses to have a general Organization Committee consisting of from thirty to sixty members who were, as a rule, well known geologists or mining engineers of the country in which the Congress was being held.

"In the case of the Twelfth Session a general meeting was called on December 2nd, 1910, and it was there decided that owing to the long distances in Canada it was best to elect a small central committee that would act as an Executive Committee and to give this Executive Committee authority to appoint any other committees that might be necessary.

"The Executive Committee, towards the end of last year, felt that it was time to have a more general committee and therefore asked various gentlemen throughout Canada to become members of the Organization Committee with the results of which you are aware.

"The chief duties which the Executive Committee had in mind for the Organization Committee were:

1st. The formation of local committees at various points which excursions of the Congress will visit.

2nd. General assistance in making arrangements for the Congress and in carrying out these arrangements.

3rd. Assistance, if necessary, in raising funds to assist in financing."

### Duties of Local Committees.

The General Secretary read the following report which was adopted without discussion.

"Local committees will be formed at the instance of members of the Organization Committee or in places where there are no members of the Organization Committee then by arrangement with the Executive.

"The duties of the local committees are to make all necessary local arrangements acting in co-operation with the Executive Committee and with the leaders of excursions. Before any arrangement is actually complete it should be communicated to the Executive Committee through the secretary in order that there shall be no confliction of plans.

"With regard to funds any entertainments or arrangements which are of a purely local character and which would not be undertaken by the Congress as a whole in the ordinary course of events must be financed locally but other liabilities, provided they have been previously approved by the Executive, will be assumed by the Executive. For example, the hire of carriages between the station and the point of interest which is planned in the excursion would, if necessary, be paid by the Executive Committee as the expenses would be considered part of the excursions. All local entertainments such as Indian plays which are of purely local interest and supposed to be offered by the people of the place would have to be financed locally.

"At the time of the excursions it is expected that the Executive will be represented on each excursion by a secretary and if this plan is carried out the local committee will deal direct with the secretary of the excursion in each case.

"In the formation of local committees it is requested that local branches of the Canadian Mining Institute as well as various scientific societies as far as possible, be represented. Local committees should not be too large or if it is found advisable to have large committees then an executive should be chosen to carry on the work."

**Places at Which Local Committees are Necessary.**

The General Secretary read a list of places at which local committees were necessary. This list was added to by various members of the committee present and the following list was adopted it being understood that local committees can be formed at any other places as and when required.

Nova Scotia—Sydney, Halifax.

New Brunswick—St. John, Moncton.

Quebec—Quebec, Sherbrooke (for the Eastern Townships), Montreal.

Ontario—Ottawa, Toronto, Kingston, Sudbury, Niagara Falls, Hamilton, Collingwood, Cobalt, Porcupine, Kenora.

Manitoba—Winnipeg.

Alberta—Medicine Hat, Calgary, Edmonton.

British Columbia.—Nelson, Kamloops, Vancouver, Victoria.

Yukon Territory—Dawson City.

Dr. Goodwin thought it advisable to add Michipicoten to the list and that a visit should be paid to this district. Dr. Goodwin thought that the Lake Superior Corporation would be very glad to assist and that we could visit Sault Ste. Marie and that we could travel by the Algoma Central Railway to Michipicoten and then reach the main line of the Canadian Pacific Railway at Hobon.

Mr. J. A. Dresser stated that he was quite sure that the Lake Superior Corporation would be glad to do anything in their power and the Algoma Central Railway had already promised transportation facilities should we require them. It was finally decided to leave the question of an excursion to Sault Ste. Marie and Michipicoten to the Executive Committee.

**Special Names to be Placed on Local Committees.**

The General Secretary read a geographical list of members of the Organization Committee, Honorary Councillors, and Leaders of Excursions. It was thought that local committees could be formed from this list with such other persons as it may be considered advisable to ask.

Mr. James White stated that in each place where there is a branch of the Canadian Mining Institute the chairman of such branch should be added to the committee. Various other names were suggested including Sherbrooke: Mr. George R. Smith of Bell Asbestos Mines and Col. J. J. Penhale. Victoria: Mr. W. J. Sutton, chairman and E. Jacobs, secretary, Western Branch of the Canadian Mining Institute. Winnipeg: A. J. Merrill, member of the Canadian Institute and T. R. Deacon, Mayor of Winnipeg, member of the Canadian Society of Civil Engineers and at one time considerably interested in mining.

Regarding the formation of local committees, an animated general discussion took place in which most of the members present took part. It was finally decided on the suggestion of Mr. Lindsey that the members of the Organization Committee and Leaders of Excursions present should meet after lunch and arrange for the local committees by forming themselves into groups according to Provinces.

**Extraordinary Duties of Any Particular Local Committee.**

Various local committees will have special duties peculiar to themselves and not provided for in the general duties. As examples of this the General Secretary read the following notes:

The Toronto Local Committee will have a great many extra duties incidental to the fact that the Congress is meeting in Toronto.

A day is spent at Ottawa, and the Ottawa Local Committee will be expected to assist in securing suitable hotel accommodation.

A day will be spent in Montreal, and the Montreal Local Committee will be expected to assist in securing suitable hotel accommodation.

It is possible that the train for excursion C. 2 will have to be shortened at Kootenay Landing, and if this is the case the Nelson Local Committee will be expected to find accommodation for the members who are deprived of their sleeping cars.

**Financial Requirements.**

This matter had already been dealt with in Mr. Lindsey's address earlier in the morning and Mr. Lindsey stated that he had nothing further to add to his remarks.

**Programme of the Twelfth Session.**

The programme of the Twelfth Session as printed and distributed on February 7th, was read and adopted, subjects to such revision as may, from time to time, be necessary.

**Local Memorial.**

In the temporary absence of Dr. Barlow, who had an appointment in connection with the Canadian Mining Institute meetings, Mr. Brock read the following memorandum from the Minutes of the Thirteenth Meeting of the Executive Committee, held in Ottawa on February 1st.

"Dr. Barlow reported that this Committee recommend that a memorial plate be erected in Perce on the occasion of the visit of the Congress and that a tablet be placed in the Victoria Memorial Museum on August 1st on the occasion of the visit of the Congress and that the expenses be defrayed by subscriptions from members of the Organization Committee. It was left to the Logan Memorial Committee to continue their work regarding the memorial, including the subscriptions to be secured."

He estimated that the cost of the two tablets would amount to a total of about three hundred dollars, which amount should be collected by the Organization Committee.

Mr. Ferrier thought that this amount could easily be secured from the members and ex-members of the Geological Survey. Mr. Brock replied that in his opinion the memorial to the late Sir William Logan would be more honoured if the subscriptions were collected from a wider circle.

The President spoke in the same strain pointing out that it was originally the suggestion of Dr. John M. Clarke, a former member of the Geological Survey of Canada. Dr. Clarke's suggestion being that in the course of excursion A.1. a tablet should be erected at Perce where so much of Sir William Logan's work had been accomplished.

Dr. Barlow, who had now returned, made a few remarks eulogizing Sir William Logan as one of the greatest economic and scientific geologists. Dr. Barlow was of the opinion that the amount required should be raised by subscriptions from the Organization Committee.

Mr. Ferrier suggested the erection of a rough stone monument with a tablet in front of the Museum in Ottawa. After further discussion it was moved by Mr. W. Fleet Robertson, seconded by Mr. W. F. Ferrier and carried:

That the Logan Memorial Committee consisting of Messrs. Barlow, Brock, Coleman and Miller be instructed to proceed with the arrangements for the erection of suitable memorials to the late Sir William Logan, the locations and characters of the memorials to be left to the named committee and that the members of this Organization Committee guarantee the expenses up to the sum of five hundred dollars.

### Announcement of Afternoon Session.

The President announced that the Leaders of Excursions were to meet in the afternoon at 3 p.m., and that after this meeting there would be another meeting of the Organization Committee to consider the reports of the provincial sub-committees regarding the local committees which were to be made by the provincial sub-committee who were also to meet this afternoon acting on Mr. Lindsey's recent suggestion.

The meeting then adjourned.

### Luncheon.

Luncheon was served in a private dining room at the Chateau Laurier at 1.10 p.m. The Right Hon. R. L. Borden, and the Hon. Frank Cochrane, two of the Honorary Vice-Presidents were present and made brief addresses in which they assured the members of the committee both of their personal and official interest in the Congress. After the luncheon the Ministers made a point of meeting many of the members and discussing the Congress affairs with them.

### Afternoon Meeting—Local Committees.

As arranged before luncheon the members of the Organization Committee formed themselves into groups according to Provinces and discussed the matters of Local Committees and additional Guides to excursions.

The Organization Committee met again about 5 p.m., to consider these reports and various Local Committees were suggested and names added. As this matter has, necessarily, to be proceeded with further the list is not given in these minutes, but when further completed will be printed and distributed in the form of a separate leaflet.

### The President's Closing Remarks.

The President took occasion to state that the Executive Committee would be glad to receive special reports dealing with subjects of geological or mining interest for distribution at the time of the Congress. He mentioned that it would be a good policy for commercial companies connected with the mineral industry to have a number of descriptive pamphlets prepared for the use of members of the Congress. He also mentioned that at the Swedish Congress picture post cards had been printed and distributed which showed scenes of particular beauty or mineral or geological features of interest.

The meeting then adjourned.

R. W. BROCK, General Secretary.
W. S. LECKY, Secretary.

# THE "DE RE METALLICA" OF GEORGIUS AGRICOLA.*

## A REVIEW

In the pride of our modern achievements we are prone to look with pitying eye upon the seemingly meagre progress made by man in centuries past. It tittivates our self-esteem to believe that we are whole heavens above the generations that have gone. A wise Providence has ordained, however, that we should not be without salutary lessons in humility. And it is with much humility that the readers of **De Re Metallica** turns the last page of that remarkable book.

Three and one-half centuries, ago, Georgius Agricola, a native of Saxony, gave to the world the first edition of "De Re Metallica." To be exact, the work appeared in the year 1556. It was the fruit of twenty years' investigation, observation and practice, and it embodied the best current knowledge of mining and metallurgy. Nor was it superseded until more than two centuries had elapsed.

Strange to relate, this noble volume, which was written in Latin, was translated only into German and Italian. Dating not later than the latter part of the seventeenth century, all these translations were inaccurate and inadequate. Particularly was this the case with the first German translation.

Briefly, although in a general way, Agricola's *magnum opus* has been known to the scientific world for long, and although there are many Latin copies extant, yet until now no brave spirit has girded up his loins for the task of rendering it into any modern language. Thus there has remained almost unseen and unused one of the chiefest jewels of scientific literature.

It has remained for a mining engineer, well known to all readers of current technical books, assisted by his wife, to open for us the treasure-house of **De Re Metallica**. Mr. Herbert Clark Hoover, whose name is familiar to us as the author of "**Principles of Mining,**" and his wife, Lou Henry Hoover, are the two devoted transliteraters of Agricola. To them we owe the appearance, belated but all the more welcome for that, of the magnificent volume that has just been issued in London. Mr. Hoover is a particularly sane and thorough engineer and writer. Mrs. Hoover, by a most fortunate accident, is an accomplished Latinist, and, in addition, a person of much scientific knowledge. No combination could have been more fortunate. Five years of intermittent, though arduous, labour were devoted to the execution of the idea—an idea conceived and carried out entirely in the interests of scholarship.

"We do not present **De Re Metallica,**" say the authors in their preface, "as a work of 'practical' value. The methods and processes have long since been superseded; yet surely such a milestone on the road to development of one of the two most basic of human industrial activities is more worthy of preservation than the thousands of volumes devoted to records of human destruction. . . . . If the work serves to strengthen the traditions of one of the most important and least

*Georgius Agricola De Re Metallica.—Translated from the first Latin edition of 1556 with Biographical Introduction, Annotations, etc., etc., by Herbert Clark Hoover and Lou Henry Hoover.—Published for the Translators by the Mining Magazine, London.—For sale by The Canadian Mining Journal, Toronto, Canada.

recognized of the world's professions we shall be amply repaid."

* * * * *

As mentioned above, Agricola spent twenty years in gathering and collating material for his book. It is a workmanlike survey of mining and metallurgy as they were practised in his day. The admirable clarity of his mind, and his equally admirable freedom from the charlatanism, superstition, and sciolism of his age are outstanding qualities. Not the least manifestation of his genius is the facility with which he coins factitious Latin names for implements and phenomena never christened by the Romans. But most interesting of all is the evidence, shown on almost every page, of the fact that the author had the real good of the mining industry at heart and that he had resolved to neglect no manifest detail that might make his presentation clearer to his readers.

**De Re Metallica** is divided into twelve books. "The first book," to quote Agricola's own words, "contains the arguments that may be used against this art [mining], and against metals and the mines, and what can be said in their favour. The second book describes the miner, and branches into a discourse on the finding of veins. The third book deals with veins and stringers and seams in the rocks. The fourth book explains the method of delimiting veins, and also describes the functions of the mining officials. The fifth book describes the digging of ore and the surveyor's art. The sixth book describes the miners' tools and machines. The seventh book is on the assaying of ore. The eighth book lays down the rules for the work of wasting, crushing and washing the ore. The ninth book explains the methods of smelting ores. The tenth book instructs those who are studious of the metallic arts in the work of separating silver from gold, and lead from gold and silver. The twelfth book gives us rules for manufacturing salt, soda, alum, vitriol, sulphur, bitumen and glass."

The author explains frankly that of course he has not fulfilled this enormous task, although he has done his best. He alludes to the large expense to which he was subjected, particularly in the matter of hiring illustrators to delineate the forms of "veins, tools, sluices, machines, and furnaces. . . . . lest descriptions which are conveyed by words should either not be understood by men of our times, or should cause difficulty to posterity, in the same way as to us difficulty is often caused by many names which the Ancients. . . . . have handed down to us without any explanation." This is characteristic of Agricola. His habit of mind was direct, searching, and honest. We shall see other illustrations of this as we proceed. He trusted only to the evidence of his own senses, or to the statements of persons on whom he knew he could rely.

Book I. is in effect a defense and eulogy of "the metal industries." It is replete with quotable passages. So rich is it that only with difficulty can choice be made. First, the author proves the essential dignity of mining. The miner must know something of "Philosophy" (geology), of medicine, of astronomy ("that he may know the divisions of the heavens and from them judge the direction of the veins"), of surveying; of "Arithmetical Science;" of architecture; of drawing; and, of the law, "that he may claim his own rights, . . that he may not take another man's property and so make trouble for himself, and that he may fulfil his obligations to others according to the law." In a word, Agricola defines the qualifications of a mining engineer and defines them well.

Mining, even in the year 1556, had its detractors. Because "scarcely one in a hundred who dig metals or other such things derive profit therefrom," and because others deceive themselves with ungrounded hopes superficial critics damn the whole industry. Agricola rises in protest. Even husbandmen choose carefully their soil and their crops. Care and attention minimize the risk of loss in mining, and are equally necessary. The ignorant and incompetent lose both time and trouble. The informed rarely lose either.

To prove the stability of mining, Agricola instances the gold and silver mines of Schemnitz and Cremnitz that had then been worked for 800 years; while the New Schonberg at Freiberg dated back beyond the memory of man. True, a miner might be disappointed in one vein, but he can always "dig another vein, if fortune does not amply respond to his prayers in the first case." And, though the business of mining may be less reliable than agriculture, is it not, asks he, infinitely more profitable? As for the risks to human life (and they must have been many in those far days!), accidents, asserts Agricola, happen "only in so far as workmen are careless." In like manner is every argument against mining disposed of. The classics are drawn upon profusely in praise of the metals. And to bring the discussion (which includes some really sage advice on mining shares) to an end, it is shown that "certainly, though it is but one of ten important and excellent methods of acquiring wealth in an honourable way, a careful and diligent man can attain this result in no easier way than by mining."

Book II. opens with "more ample information concerning the miners." In the first place "it is indispensable that they should worship God with reverence." It is God's decree, says Agricola, that those who know what they ought to do and how to do it properly, usually meet with good fortune, and *vice versa*. If a man owns a mine himself, he must visit it frequently, even work with his own hands. The diligent workmen are to be praised by the owner. His comings and goings should be announced so that the workmen may not be frightened by his unexpected presence.

With syndicates as with private individuals, the risks of investment should be considered carefully and some person or persons held responsible. And so on. Preliminary considerations such as roads, topography, fuel, timber, water, etc., are touched up, and the outward and visible signs of the existence of veins are outlined. "The forked twig," or divining rod, is given a page or two, and the summing up is one of the best things in the whole book. "A miner, since we think he ought to be a good and serious man, should not make use of an enchanted twig, because if he is prudent and skilled in the natural signs, he understands that a forked stick is of no use to him, for as I have said before, there are the natural indications of the veins which he can see for himself without the help of twigs." Could the whole matter be summed up more beautifully!

In Book III., Agricola discusses "veins and stringers, and the seams in the rocks." Roughly, the fissure vein was the "vena profunda;" the bedded deposit, the "vena dilatata;" the impregnation, the "vena cumulata;" and the stringer, the "fibra." The relation of rock structure to the veins is a matter of discussion. So also is the compass. The book concludes with a dissertation on veins and stringers as they actually occur.

(To be continued.)

# THE CYANIDE PROCESS IN CANADA*

By HERBERT A. MEGRAW, New York.

Cyanidation is a comparatively new process in Canada. Until quite recently, in Eastern Canada at least, the gold and silver production was relatively small, and metals were in the main recovered as by-products from the reduction of base metals. In British Columbia, however, the cyanide process has been employed for some time past in the treatment of gold ores. The utilization of the process to any considerable extent in Eastern Canada was occasioned by the development of metallurgical practice in connection with the treatment of the silver ores of the Cobalt district. These ores, consisting as they do, of a chemical and mechanical mixture of silver with iron, sulphur, manganese, nickel, cobalt, arsenic, antimony and sometimes small quantities of mercury, present to the metallurgist an unattractive combination for cyanidation; in fact, their amenability to such treatment would not recommend itself to one at first glance. Naturally enough, the shipping of the rich ore to smelters and the concentration of the lower grades into a product rich enough to ship, were the first processes in use; but eventually experiments with cyanide solutions were made and now cyanidation is an established metallurgical means of recovering silver from the Cobalt ores. There is little doubt, however, that it has not yet by any means reached its apex of efficiency nor its widest application. In the early stages of application this condition is to be expected and, since the ores present a metallurgical problem which cyanidation in no other instance has been called upon to solve, it is extremely probable that some variations of methods will eventually be devised peculiarly adaptable to ores of this complex character and differing radically from usual practice. Until now methods in the Cobalt district have been largely those already in general use. An exception, however, is afforded in the case of practice at the Nipissing high-grade mill, now well known throughout the metalurgical world, where a peculiar combination of processes is employed and applied successfully in the treatment of extremely rich silver ores. But the method here can scarcely be described as cyanidation, for the greater part of the recovery is effected by the amalgamation. It is nevertheless, an example of the fitting of a process to the material to be treated and as such deserves special praise and study. Presumably the system in use at this mill is familiar to all interested in the subject, but a brief review of its principal features may be permissable.

The ore, the values in which are as high as 3,000 oz. silver per ton, is first crushed dry in a ball mill to a point where it will pass a 20-mesh screen. It is then sampled and stored until required for treatment. The first step in actual metallurgy is the charging of the crushed ore into a tube mill together with mercury, a 5% cyanide solution and pebbles for grinding. The tube mills thus converted into what is practically an amalgamating barrel, with the addition of the grinding feature, unusual in combination with amalgamating systems.

The whole charge thus made is sealed in the tube mill and the machine started. The revolution of this tube at usual speed naturally results in a rise of temperature, and it is possible that this rise might exceed the point of assisting amalgamation and become positively dangerous to successful results but for the fact that it is controlled to some degree by passage through the mill of compressed air, which readily absorbs part of the heat and removes it. It would be natural to expect a large loss of mercury in this procedure, due to "flouring" or "sickening," but it is stated that this does not occur, the loss is not great and is presumably offset to some degree by the small amount of mercury contained as mercury-silver amalgam in the ore.

The action within the tube is probably that of liberation of the metallic silver by the fine grinding and its immediate amalgamation with the mercury, which is maintained in an active state by the temperature and the strong cyanide solution. The latter keeps the mercury clean by dissolving those compounds which when present convert it to fine globules and prevent their coalescence, a condition in which it is known as "floured" or "sickened" mercury. It is undoubtedly true that the cyanide solution thus becomes charged with many elements which it carries into the subsequent treatment. This treatment consists of agitating the now finely ground ore, after the removal of the mercury and amalgam, in the usual way in tanks with cyanide solutions.

As these solutions are used repeatedly it is probable that there is some point where these foreign elements, or a portion of them are removed; otherwise accumulation would result to such a great extent that the solutions would lose their efficiency. The natural place to anticipate difficulty would be in the precipitation department. Zinc shavings are used for precipitation, and it is noticeable that during the passage of the solutions through the boxes a precipitate, light in weight, is formed which does not remain to any great extent in the box but passes through it and settles in the large, quiet area of the sump tank. Analysis of this precipitate has shown the presence of practically all of the elements mentioned as contained in the ore. This occurrence will account for the removal of many disturbing elements, and the fact that the pulp after leaving the tube is diluted with this precipitated solution makes the additional dissolution of silver in the tanks readily understood. In addition to the elements removed in this way from solution, it is altogether likely that some of the elements which are at first dissolved in the cyanide solution will be precipitated as sulphides, due to the large sulphur content of the ore. This will account, certainly, for the removal of some of the mercury dissolved, which will form an insoluble sulphide, and also explains the non-use of lead salts during cyanidation, as is usual in most silver treatment plants, the mercury efficiency taking its place.

The total recovery effected by this combination of processes is said to be about 99%, possibly more at times. The amalgamation is responsible for about 97%, the cyanide recovery being comparatively small, but nevertheless well worth while on account of the extremely high original content of the ore.

The whole scheme of treatment is ingenious and reflects great credit upon the metallurgists responsible for its devising, namely, Mr. Charles Butters, assisted by Mr. G. H. Clevenger and Mr. James Johnston.

Three other Cobalt mines are practicing cyanidation in some form and degree. These are the Buffalo Mines Co., the Dominion Reduction Co., and the O'Brien. The Buffalo uses both concentration and cyanidation, treating by cyanide only the slime formed during crushing and grinding, which is not more than about 20% of

*Read at Ottawa Meeting, C. M. I.

the total ore crushed. About 80% to 85% of the silver contained in this slime is reported to be extracted by cyanidation in the usual form, using air agitation tanks. Steam coils are employed in the tanks to assist solution of the silver, which is a necessary procedure during the cold season and may be of practical utility at other times. The Buffalo company is installing or has now installed an auxiliary plant for the treatment of rich products by a system similar to that in use at the Nipissing.

At the O'Brien mill concentration of the total ore is followed by cyanidation, the usual methods being followed, all the ore being reduced to a point where it can be agitated. At this mill an unusual feature is the precipitation, aluminium dust being used instead of zinc, otherwise the method is the same. The advantages are that one ounce of aluminium dust will precipitate three ounces of silver and that the resulting precipitate can be melted without the use of flux, producing a high grade bullion. As the cost of the aluminium dust is about three times that of zinc the advantage is apparently reduced to the ease and economy of melting, which may be important and which certainly deserves investigation, if it has not already received it.

At the mill of the Dominion Reduction Company a most careful system of concentration before cyanidation is followed.

At the new mill of the Nipissing Company, completed since the writer's visit to the district last autumn, the plant is designed to cyanide ores of lower grade, 25 to 30 oz., without preliminary concentration, other than jigging, making a total slime product, and to make use of some chemical innovations. Chemical improvement is of vital importance to the successful cyaniding of these ores.

In addition to the mills already using the cyanide process, the large number of concentrating plants in operation are producing a quantity of tailing of appreciable value which might be amenable to cyanide treatment in some form. This material being already crushed and in condition for economical handling should yield a further profit. Some chemical improvement by means of which cyanide losses could be reduced and extraction increased would be of immense value.

In this connection attention may be called to the increased extraction of silver at the Tonopah and other silver treating mills by heating the solutions to 120. Also the stress laid by some western metallurgists who are convinced of a notable improvement in extraction by crushing ores in water, removing the water so far as possible, and then applying the cyanide solution. It seems possible that a preliminary application of some solution might result in increased efficiency, and it is certainly worth while searching for a method that can be applied successfully to these ores. The Cobalt ores differ so much from those to which these measures have been applied that it is natural to expect a different procedure in treatment and there is room for further experimentation.

The situation as regards cyanidation is entirely different in the Porcupine district. Here the principal value is in gold which is contained in a quartzose ore, comparatively clean and presenting no metallurgical difficulties. The two mills at present using cyanidation on a large scale, the Dome and Hollinger, are accomplishing the same metallurgical result by two different mechanical means. At the Dome, plate amalgamation is employed to recover the free gold which is in particles too large for dissolution in cyanide solutions within a reasonable treatment time. At the Hollinger this material is recovered by concentration on tables, and subsequent treatment of the concentrate by pan amalgamation. At the Dome mill the ore is crushed in water in order to assure successful amalgamation; while at the Hollinger, crushing is in cyanide solution. It has been found at the Hollinger that very little gold escapes from the tube mills, but, due to its weight, is retained in the tube mill until ground fine enough to be dissolved. This will probably make some change in procedure advisable.

At the Dome mill the water crushing is objectionable on account of the fact that it necessitates the introduction of a large amount of water into the cyanidation cycle, and this must later be discharged with the residue and will then contain considerable cyanide with possibly some dissolved gold. The probabilities are that the amalgamation system is unnecessary viewed in the light of the experience of the Hollinger. Even if it is not, amalgamation may be successfully performed in cyanide solutions, as is done at the Liberty Bell mine at Telluride Colorado, with eminently satisfactory results.

In Canada, gravity stamps appear to be regarded as the only feasible crushing machine. The trend of the time, however, is towards discarding stamps on the grounds of expense and trouble of operation. The writer believes that, in general, other crushing systems are more economical and more satisfactory. Even in South Africa, where the heavy stamp finds its chief advocates, some metallurgists are earnestly recommending a change. Either rolls or Chilean mills, or a combination of both will be found, it is believed, to have advantages aver stamps. It is to be hoped that in the near future some experiments may be made that will determine finally this point.

# CANADIAN MINING INSTITUTE—WESTERN BRANCH

The fourteenth general meeting of the Western Branch of the Canadian Mining Institute was opened at Nanaimo, Vancouver Island, B.C., on the afternoon of March 4. In the unavoidable absence of the chairman of the branch, Mr. M. E. Purcell, of Rossland, who was attending the annual meeting of the Institute in Ottawa, Mr. Thomas Graham, chief inspector of mines for British Columbia, presided.

After a few words from the chairman, Mr. Thos. R. Stockett, general manager for the Western Fuel Co., owning and operating three local coal mines, extended a welcome to the visitors. In the course of an interesting address, Mr. Stockett mentioned that Nanaimo is the oldest coal-mining centre on the Pacific Coast. Before the advent of white men, coal was mined by Indians; the earliest commercial coal mining here, however, was done by the Hudson Bay Co. While coal was found at Nanaimo in 1849, it was not first mined in a systematic way until 1852, but mining had been continued there ever since. As stated, the first operator was the Hudson Bay Co., which, a few years later, sold the Nanaimo mine to an English company, the Vancouver Coal Co., which was reorganized in 1899 as the New Vancouver Coal Co., while in 1902 the Western

Fuel Co. acquired the property. Coal was reached in No. 1 mine, known as the "grand old mine of British Columbia," in 1883, so that mine had been operated for 30 years. To-day there is as much coal in sight in that mine as has been taken out of it, so it is difficult to prophesy what its future will be. During the past month a record was made of 1,700 long tons in a single day's hoist, while the average daily output for the week had been 1654 tons. On a similar basis, working 300 days in the year, an annual output of half a million tons could be made, and it is thought the days for such a production are not far distant. The company is now opening a new mine, known as the Reserve Shaft, on an Indian reserve four-and-a-half miles from its shipping docks, where there is a splendid bed of coal at a depth of about 1,000 feet, which will shortly be reached by the shafts now being sunk. This mine is being equipped for an output of 2,000 tons of coal a day. Mr. Stockett mentioned, further, that the company takes a deep interest in everything tending to the safety of the men in its employ. Mine rescue oxygen breathing apparatus was provided by the company and men trained in its use before the Provincial law requiring this protection for the men was enacted. The local Mutual Improvement Association, established by the company's mine employees for the discussion of mining subjects, has been encouraged; also every assistance has been given to Mr. F. Napier Denison, of the Dominion Meteorological Office, to carry on investigations and make observations in the mine, in connection with his theory that there is relation between earthquakes and earth-movements and mine disasters. Information was also given showing the low death rate in the company's mines.

After the chairman had made reference to the assistance and co-operation given so readily by the United States Mine Rescue Training Station officials at Seattle, Washington, prior to the establishment of the local mine-rescue corps, an interesting and instructive paper was read by Mr. Geo. Watkin Evans, of Seattle, on the Groundhog coal field in the northern part of Skeena district, British Columbia, in which field Mr. Evans spent the summer of 1912 examining coal lands for clients. A series of lantern slides showed the rough topography of the country, and in some instances the nature of the rock formations.

A paper on "The Best Methods of Mining Coal Under Various Conditions," prepared by Mr. Alexander Sharp, of Vancouver, B.C., for the annual meeting, Ottawa, was, by the courtesy of the secretary of the Institute, presented. This was one of several Mr. Sharp had undertaken to prepare; it dealt largely with longwall mining, and in it were references to the conditions in parts of the Nanaimo field, Mr. Sharp having been manager of a local coal mine some years ago.

### Tuesday Evening Session.

On Tuesday evening, the proceedings were opened by Mayor Shaw officially welcoming the Institute and its guests to Nanaimo, and then at some length reviewing the progress of the coal mining industry of the province, besides giving information concerning coal mines on Vancouver Island.

Mr. Henry Clark, M.I.Min., E., Canadian manager for Head, Wrightson & Co., of Stockton-on-Tees, England, colliery and mining engineers, next read a paper on "Modern Surface Equipment of Coal Mines," in which he gave a review of his work and experience in connection with the surface equipment of collieries in different parts of the world. He dealt with head-frames, pulleys, keys, cages, simultaneous banking, safety devices on cages, air-boxing for upcast shafts, safety detaching hooks, patent tipplers, mining cars, screens, picking belts, horizontal screens, coal-washing, storing and shipping coal, maintenance, etc. The address was illustrated by numerous landern slide views, some of them showing bankhead equipments as a whole, and other details of construction, etc. In addition several models were shown. The address was well received and many questions were asked and replied to at its close.

### Wednesday's Proceedings.

On Wednesday morning a visit was paid to the new Reserve Shaft mine, under the guidance of Mr. T. R. Stockett, general manager; Mr. Thos. McGuckie, general superintendent, and Mr. A. S. Hamilton, master mechanic. Both of the new shafts are 10 x 26 feet in the clear, divided into three compartments—two for hoisting and one for air. Each has an area of about 100 square feet, and in this connection it was pointed out that it is unusual to have the air shaft as large as the main shaft. Hoisting engines, which were installed shortly after sinking was commenced and since used in this work, were made by Andrew Barclay & Sons, Ltd., Kilmarnock, Scotland; that for the main shaft is 30 x 60, with 14-foot drums, and that for the air shaft 20 x 54, with 12-foot drums. Both are provided with all the latest known devices for preventing overwinding, checking speed, and automatic closing off if the hoist engineer be neglectful or disabled. The Canadian Rand compressor is compound steam, compound air, 2,500 cubic feet capacity. Two h.r.t. boilers 84 in. x 16 ft., each with 104 4-inch tubes, generate steam; four more will be added to make the full battery. A double Sirocco 90-inch fan is being put in, capacity 400,000 to 500,000 cubic feet of air. The standard gauge railway from the mine to the company's shipping docks crosses the Nanaimo River near the mine on an overhead Howe truss bridge having two 150-ft. spans, with centre pier; this bridge has been built strictly in accordance with the requirements of the Railway Act of British Columbia. The total expenditure to date on railway, shaft-sinking, machinery, etc., has been approximately \$500,000, and it is estimated that it will require a further outlay of fully \$300,000 to place the mine in condition to regularly maintain the projected output of 2,000 tons of coal a day.

After lunch the party was taken in the company's launch to Malaspina's Gallery, a striking natural grotto or balcony cut out of the sandstone rock on the northwestern shore of Gabriola Island by the action of wind and wave, more than 100 feet long by about 10 feet wide. Capt. Alexandro Halaspina, an accomplished Italian navigator, in the service of Spain, is stated to have discovered this natural phenomenon when hereabouts in 1791, engaged on an expedition of survey and discovery. He went as far north as Malaspina Glacier in Alaska, between Mt. St. Elias and the sea, the glacier having been named after him.

### Mine-Rescue and First-Aid Work.

On Wednesday evening Mr. J. F. Menzies, general superintendent for the Northwestern Improvement Co., of Roslyn, Washington, U.S.A., gave an address on mine-rescue and first-aid work, and he was followed by Mr. P. B. Ashbridge, St. John Ambulance Association instructor in first-aid work to the Canadian Pacific Railway employees west of Winnipeg. Mr. Matthew Gunness, of the local Mutual Improvement Association, read a paper on "Mine Accidents and How to Prevent Them." Instructive discussion ensued on each of these subjects.

During the evening the chairman, Mr. Graham, who before he became chief inspector of mines was general superintendent for the Western Fuel Co., stated that the company has sixty-five "graduates" trained in the use of mine-rescue apparatus. In the Province of British Columbia there are now eighty-eight sets of oxygen breathing appartus—49 two-hour Draeger, 30 half-hour Draeger, and 9 Fluess. As there are 7,130 persons employed in the coal mines ,this gives one for every 81 persons employed. Fatal accidents in coal mines in British Columbia during the last three years had been: In 1912, 3.93 per 1,000; in 1911, 2.32 per 1,000; in 1910, 3.61 per 1,000. The lower ratio in 1911 was due to the fact that during about seven months of that year most of the coal mines of the Crow's Nest Pass were inoperative, owing to a strike of the miners, the quantity of coal produced that year from those mines having been 800,000 tons less than in 1912. For a 10-year period, 1903-1912, the death rate had been 5.078, atributable to—falls of roof, 6 (21.43 per cent.): falls of coal, 3 (10.72 per cent.); mine cars and haulage, 9 (32.14 per cent.), and 18 (64.32 per cent.); explosives 7 (25 per cent.) miscellaneous, 3 (10.78 per cent.). Seventy-five per cent. of the accidents—caused by falls of roof and coal land hauluage—were avoidable, and were due to negligence on the part of those directly affected, or to lack of discipline of officials. Mr. McGuckie gave particulars of the progress of mine-rescue training at Nanaimo.

Before adjournment, Mr. E. Jacobs, secretary of the branch, heartily thanked those who had taken part in the varied and interesting program, especially the visitors from the State of Washington, and, to Mr. Stockett and the other residents of Nanaimo who had co-operated to make the meeting the distinct success it certainly had been.

Adjournment was then made to another hall where Mr. Stockett had provided supper for between 100 and 150 present, and this was folowed by a smoking concert, the excellent program of which was carried out chiefly by employes of the Western Fuel Co.

## MORE POETRY

[Note.—The following verses were written by Mr. A. S. Hamilton, master mechanic for the company, and read by him at a banquet of the officials of the Western Fuel Company, Nanaimo, Vancouver Island, British Columbia. While the occasion referred to was not in the immediate past, the sentiments expressed are live ones to-day, as they were when the writer of the verses first read them.]

—o—

**Response to the Toast—"The Surface Department."**

In looking around me for something to say
In response to this toast;
I'm hoping to utter no language that may
Look to you like a boast;
For rather, I think, do we surface men feel,
That here on the Tqp we've the best of the deal;
We're content to be reckoned a spoke in the wheel,
A unit at most.

But just for a moment we ask for your ear,
Since we're in the act;
And would like to remind every mining man here,
With tenderest tact,
That though we don't share in the strenuous pace,
That exists down below in your hell of a place,
The troubles don't end when coal leaves the face;
And that is a fact.

According to what the geologists say,
It duly appears,
The coal has been formed and hidden away,
For millions of years;
And often we feel that their theory's right,
It so clearly explains why the coal it takes fright,
And balks just as soon as it hits the daylight,
And this valley of tears.

Now everyone knows just how fractious it gets,
And how eager to shine.
Though we handle it just like a child in the pets
All to hold it in line.
When we read of its energy, bottled and pent,
And its frantic ambition to find a clear vent,
We're ready to swear that the most of it's spent,
Right here at the mine.

How they manage at 'Frisco there's few of us know,
And less of us care,
For long before they have their troubles below,
We've had our share.
From the foot of the shaft to the ship at the dock,
'Tis nothing but one constant stubborn balk,
And it often exhausts all the patience in stock,
And would more if it dare.

Yet do not assume that as martyrs we pose;
We make no such appeal;
We're paid for our work, and as everyone knows,
That's all in the deal;
But to-night we make bold to present to your view,
A blue-jumpered, plain-looking chap in our crew,
To whom we feel certain your homage in due;
The man at the wheel.

He stands at his throttle from morning till night;
You ne'er saw him flinch;
And the swift plunging cages that're hid from his sight,
He'll land to an inch;
The big creaking drums that would like to run wild,
He handles them just as a woman her child,
And they know he's the boss; but though usually mild,
He can hurt in a pinch.

In the morning he tests every lever and screw,
Each cotter and pin;
And he makes them all swear they will stand by him [true,
Through thick and through thin.
The turbulent parts of his monster machine,
He pats on the back—though he lectures them keen,
While the big, sombre dial stands watching the scene
With satisfied grin.

By a curious blend of coincident law,
And mechanical rules,
His nerve is of steel and as free from a flaw
As the lever he pulls;
And you step on the cage with a confident air, [care;
And, without the least thought, place your life in his
You instinctively feel that you're safe while he's there,
At the end of the tools.

His mind is spring-loaded and ready to pop,
If the least thing goes wrong;
He'll spring like a trap should the signal to stop
Be flashed on his gong;
Yet, though he lives under this tension and strain,
And an air of excitement envelopes his plane,
The power of control, and command of his brain,
Looms up in him strong.

From the manager down we may all make mistakes,
Strange as it may seem;
Yet we may o'ertake them without any aches,
Or the loss of a dream;
But the man at the hoist must have never a trace,
Of an error, no matter how strenuous the pace;
And this truth alone should command him a place
High in our esteem.

We're obliged for your toast and 'tis pleasant to know
That we have your goodwill—
May the sentiment mutual continue to grow
While we grind at the mill;
And when in the future we socially meet,
And extend to each other those compliments neat,
We humbly request you to take from your store
Of greetings and wishes one little cup more;
An extra kind whisper of praise in the ear,
A bumper that's bigger and fuller of cheer,
The pleasantest smile you may have at command,
The kindliest, friendliest shake of the hand,
Your nicest "good day" and encouraging smile,
A clap on the back of your jolliest style;
And shower them, along with the thanks of your wives,
On the man who so faithfully handles your lives;
He's the King of the Surface Crew, Boss of the Kit,
He's the muscle and nerve, he's the man with the grit;
He's the Prince to whom each of us raises his cap,
That dungareed, blue-jumpered, plain-looking chap—
THE MAN AT THE WHEEL.

# NOTES ON MINING AND TREATMENT OF GOLD ORES

**By R. B. Lamb, Toronto, Ontario.**

(Written for the Canadian Mining Journal.)

In this paper I shall attempt to discuss broadly mining methods and metallurgical processes employed for the extraction and treatment of gold ores during recent years, and to indicate some probable lines of progress in the immediate future.

I shall not, of course, undertake an exhaustive treatment of the subject, but shall touch only such as appear to me salient points illustrative of evolution.

Gold is wisely distributed in nature in small quantities. On account of the scarcity of the metal, its resistance to oxidation, and its attractive colour, the miner has always favoured its exploitation.

Owing to the small weight of gold in a ton of material and in some instances to the difficulty of separating the metal from the gangue, special care is required to mine and treat the ores of gold without undue losses of metal. Exact metallurgical methods have been demanded and these have induced the creation of a body of technical men, who have learned to manipulate with a high degree of scientific skill.

In gold recovery, we are not so much interested in the percentage of extraction, as in the value lost in the tailing. Percentages may be misleading; tailing-values never.

Throughout the ages mining for gold has been one of man's favourite occupations. As civilization advanced and man marched industrially onward the business of gold mining became more and still more defined, until now it has assumed all the dignity of a recognized commercial undertaking, directed by scientific thought and means. But mining for gold is now, or should be, only undertaken by those who are qualified. It cannot be too often repeated, that the only opinion worth following on a gold problem—either mining or treatment—is the opinion of one trained for that purpose, namely, a mining engineer.

Engineers may differ in attainments, in training and experience; nevertheless, advice by the trained official of the problems at hand is the only direction that money, time or thought should be risked upon.

We are now at a time in the history of gold mining when we must not deal with the fantastic ventures of the promoter as with the industry of gold mining. We must only consider real mining and ore reduction.

A large part of the world's gold supply has been recovered from placers and gravel deposits of various kinds in which gold is present in the metallic state, alloyed usually with a little silver. It occurs as gold dust or grains and nuggets of varying sizes, but rarely exceeding a few ounces in weight. Gold obtained by hydraulicking or dredging is much finer than that from other gravel mining and can be readily saved.

In earlier times and still within the memory of the living, gold from the shallow deposits was recovered by washing with hand appliances, sometimes with the aid of a horse or mule. The machines used were crude and simple—generally made on the claim.

The shallow placers of Australia and America, for instance, were a boon to the miner without capital and were quickly and inexpensively worked. High recoveries were made with the simple hand appliances readily fashioned on the ground. Thus, the easily worked shallow deposits quickly disappeared and gravels, which contain only a very small amount of fine gold, are left for subsequent working. Obviously, to render these profitable, machinery for the preparation of the deposits for removal on a large scale was necessary. Thus, we find shallow placers and rich gravels, which were, at one time, very profitable to hand methods, are now exploited by hydraulicking and dredging.

Another type of workings, called in Australia "deep leads" and in California "drift mining" (generally an old river channel covered by rock formation) demanded special mining. When the gravel taken from these deposits has been brought to the surface, the separation of the gold from the matrix is as simple as with shallow placer mining.

Much of interest might be said and written on placers and deep leads and other gravel deposits carrying gold; but as the methods employed are comparatively simple and well understood, and as these deposits in the future will probably be much less important than at present, and still less important than lode mining, we will pass on to gold obtained from ores in vein mining.

Gravel mining, which is probably the simplest of mining, has called to its aid electricity and mechanical appliances used in hydraulicking and dredging. Gravels with a low-grade gold tenor offer to-day principally problems of moving material. Their exploitation is an engineering problem either of conveyance of material in large quantities by mechanical means, or by the agency of water. From whatever view point we look at gravel work, except deep lead mining, the question calls for an engineer to work out the following problems: To prepare the deposit for removal and remove it; to wash it to recover the gold; and to dispose of the tailing. The actual extraction of the gold from the gravel matrix is a matter so simple as to call for no special comment. In all rich placers and gravels, Nature has really mined the ore and placed it in defined channels or beds, concentrating the gold during deposition and rendering its removal and recovery easy and inexpensive. When the rich shallow gravels are worked out, the opportunity of the ordinary working miner to make gold mining a profitable business disappears, and the skill of the trained operator is required.

The production of gold from vein mining, on the other hand, has been steadily increasing during the past ten years and for the year 1912 we have the largest production from vein mining on record. This has been due to several causes. A large factor is the discovery and intensive exploitation of the deposits of the Transvaal. The real cause, however, appears to me to be that many deposits are of such nature that in order to return an adequate profit on the capital invested, operation on a large scale is compulsory. We have before us the evidence of a number of years of gold mining, showing that the early vein discoveries of importance were comparatively rich in gold and of limited tonnage. These were easily worked with small plant and little capital was required to return big profits on the investment. As the rich veins which were easily found (such as those of Australia and California) became worked out, larger deposits of lower gold tenor were developed and brought to the producing stage; hence, large combinations of capital involving greater development ahead of reduction processes became the practice. The development of a gold prospect, where a small amount of capital will put it on a producing and profitable basis and where the mine can be further exploited and tonnage and production increased out of profits, is a rare occurrence now. More comprehensive study and greater development with a view to blocking out tonnage ahead of a proposed reduction plant are essential factors in present day gold mining. It is becoming increasingly more difficult to mine in a small way. Capital is not attracted by small tonnage.

In the early days of California and Australia the type of ore deposit known as "free milling" best illustrates the simpler kind of vein mining for gold. In both these countries we have quartz veins carrying free and visible gold together with a small percentage of sulphides with which gold is associated. The outcrops of many of these veins were very rich and the gold readily obtained by free milling practice. The ease with which the gold was recovered and the handsome profits from operation rendered the early industry full of fascination and romance. It also retarded progress in the development of mining methods and metallurgical processes. Perhaps if we consider mining methods adopted in the gold fields of Victoria as an illustration, we will be better able to compare methods then used (and to some extent still used) with more modern methods, for instance in the west of Australia and in Mexico.

In Eastern Australia, particularly in the gold fields of Ballarat and Bendigo, when opening up a new prospect, sufficient ore is developed to justify the erection, we will suppose, of a five or ten-stamp mill and to keep it employed for about a year. If the prospect subsequently developed further ore, the mine would build itself up out of profits from this small beginning. If the property failed to develop more ore, another idle plant gave testimony to indifferent methods and shareholders were not compensated for the risk they had taken. These methods are still in vogue in the State of Victoria, although some of the more experienced operators are now convinced that it is better to develop the mine, and, as far as possible, determine what the probable life will be before building a reduction works. Old methods of stoping and handling ore underground still prevail in most of the mines. While the work accomplished is well done and the mines are worked with due regard to the safety of the workmen, they still lack the progressive spirit calling for the installation of improved equipment. Most of the mills at Ballarat were, seven or eight years ago and some are still, fed by hand. I remember when the first automatic feeder was put in a stamp mill in the Ballarat gold field. This serves to illustrate the backwardness, in some respects, of the early historical mining camps. Western Australia employed automatic feeders before many important camps in Eastern Australia would tolerate them. The splendidly trained miner of Eastern Australia in performance was ahead of his somewhat less skilled brother of Western Australia. To make up for the difference in men, machinery was generally utilized in Western Australia. This is well illustrated by machine drilling. While Eastern Australia is now employing air compression and rock drills for both development and stoping, a considerable time elapsed after the successful introduction of these methods in other parts.

The old time manager of the camp at Ballarat had a distinct prejudice against rock drills, without proper means of determining the cost between hand and machine work. He insisted that machine work was costlier than hand work. In a way, the eastern miner was right. If machine work had been introduced into eastern mines without compensating progressive introductions in other parts of the work, machine drilling would have been costlier to the eastern industry; but machine drilling once established, with all other parts of the mine working in harmony, as since adopted, has unquestionably proved more profitable to the mine owner in both eastern and western camps. Eastern Australia approved of the methods of the old practical miner and his management was the dominant factor in the operation of the mines of the principal gold fields of the country. It has not even yet escaped from the older methods. The technical man has not had a free opportunity in Eastern Australian gold camps and as a result, reliable cost data are not frequently dealt with. On the other hand, Western Australia and parts of Northeastern Australia have come under the influence of investors demanding direction by experienced engineers so that newer and better methods prevail, especially in the transportation of ore and delivery of ore from stopes and other mine workings.

Work under the old methods of Eastern Australia as stated before, is on the whole well done, and very cheap work in many places is accomplished; but through lack of the guidance of the trained engineer, this work is done on propositions that frequently do not warrant the expenditure of such energy. Yet Western Australia is fruitful in instances of the advancement of gold mining methods, particularly the application of mechanical agencies to the treatment of gold ores.

The writer was in Kalgoorlie during the period of its most interesting development and took part in the metallurgical work of the time, as well as having the opportunity to study the work of other engineers in the same field. I remember the early worries of the Kalgoorlie metallurgist when tube milling and filter pressing were first introduced. Despite all the first troubles of slime settlement, classification, etc., this was probably the greatest school of metallurgy we have ever had for gold.

Mechanical progress kept pace with chemical methods, nor were underground operations lost sight of. Kalgoorlie alone was responsible for the early success and the adaptation of filter-pressing and tube milling to the treatment of gold ores, and, as far as I know, this camp was the first to dispose of the tailings from filter pressing for stope filling. The disposal of this residue was accomplished by mechanical means with the aid of belt conveyers and was a distinct step in advancement over old methods. The utilization of tilting furnaces in bullion refining was another step in the progress of the metallurgy of this camp.

The refractory sulpho-telluride ore of this region were high-grade, and suitable smelting facilities did not exist. The mine operator was faced with a situation, underground and above ground, of this nature. Underground, owing to the friable nature of the valuable mineral in the ore, careful mining was necessary. The magnitude of the ore bodies rendered extensive mining desirable and the lack of a convenient smeltery rendered treatment on the ground imperative. Kalgoorlie, therefore, was a distinct factor in the advancement of Australian mining methods and metallurgical processes. It was the pioneer in the treatment of refractory gold and of gold-silver ores. The mining world owes an immense debt of gratitude to Kalgoorlie. The high price of labour and the difficulties of desert operation rendered the mechanical handling of ore and tailings absolutely necessary, and the scarcity and poor quality of water emphasized the necessity of improving slime settlement, they pointed the way and made it possible for brilliant investigators in the United States and Mexico to reach the present state of high efficiency.

The Rand, on account of the depth and extent of its ore deposits, taught the mining world much in the way of handling ore and developing and blocking out ore reserves far in advance of milling operations. While attending to this problem the Transvaal rested content with the metallurgy of gold as worked out by earlier practitioners, and it was not until Kalgoorlie had demonstrated the value of more progressive methods that the Rand began to adopt these measures.

The gold tenor of the quartz veins of Eastern Australia is now generally so low that further improvement can hardly be expected until operators will introduce more progressive underground methods. Stoping systems that will eliminate to a much greater extent the shovelling of ore than is in use to-day and more up-to-date methods for handling ore underground will have to be employed before further cost reduction can be expected. The principal reason for marking time is the high quality of underground labour and the comparatively low price of this labour. This held back the introduction of special machinery, and the employment of technical men who would, in many instances, have adopted different mining methods than have been employed.

California, on the other hand, probably due to the love of Americans for mechanical devices and the close contact with other mining regions of America, adopted mining schemes that were a mixture of the older ideas and of newer progressive methods. In parts of California, splendidly equipped and well managed mines with good methods are found, and at other properties, we find deplorable methods and bad operation.

It is noteworthy that both the State of Victoria and the State of California were responsible for the development in the chlorination process. This process was evolved for the treatment of sulphides obtained from concentration of the quartz ore found in these regions. Australia (particularly the camp of Ballarat) in the development of the chlorination industry gave to the world the splendid Edwards roaster, which is now used throughout the mining regions. The chlorination process was the first chemical process to give decided satisfaction to the operator. It has since been supplanted by the cyanidation process—not because the cyanidation process is more thorough in its chemical work, but because the cyanide process is easily to operate and cheaper in cost. While we may not have much use for the chlorination process in the future, no words can express the value of the process to metallurgy as pointing the way to exact chemical manipulation for gold ores.

It is important to point to the fact that the State of Colorado has some examples of both the worst and best practices in gold mining. Probably no other state in the American Union has offered to the world a greater variety of ingenious appliances for use in gold mining and metallurgy than Colorado, and it is a matter difficult to explain why this state has supplied methods and machines for a country like Mexico right up-to-the-minute in progress, and suffers operations within her own borders, which are both crude and unscientific.

The dawn of modern methods began in Australia with the treatment of the immense heaps of tailing accumulated from the mills of the fifties, sixties and seventies. Eastern Australia with its tailing heaps developed the chemical side of metallurgy and Western Australia with its desert difficulties developed the mechancial side of metallurgy. The result was a highly efficient body of trained men. These men were available for other service as soon as the great tailing heaps had disappeared. Most of these accumulated tailings of Eastern Australia carried a considerable portion of sulphides which were oxidized by exposure to the air and complicated chemical salts resulted from weathering. To obtain the solution of the gold by cyanide before its destruction by the salts of iron and to do this at a low cost, sharpened the minds of those in charge and was responsible for an evolution that those engaged in the work look back upon with the fondest recollections.

The writer was one of the first engineers in the State of Victoria engaged in cyanidation and it is interesting to recall the fact that as our literature was meagre and opportunities for studying practice almost nil, operations, particularly those of refining, were largely a matter of conjecture.

We attempted to roast zinc-gold slime in diminutive iron trays in F Battersea muffles, and we tried to treat the slime with acid in a ten-gallon hogshead. Needless to say, our early attempts were terrible failures. Precipitation by charcoal was invented and utilized on most of the accumulated tailings plants in the State of Victoria. The reason of this was the large amount of caustic soda that was necessary to neutralize acid salts. The charcoal method of precipitation worked extremely well and was a very efficient method of gold precipitation for the special conditions in that State. The accumulated tailings were a mixture of sand and slime (usually a large percentage of slime). I think that it was in Victoria that the shallow vat of great diameter was first introduced and I believe I am right in stating that the plant erected at the Black Hills mine near Ballarat had the shallowest and greatest diameter vats of the time. The depth of sand was four feet and the diameter of the vat, if I remember correctly, was forty feet. The solution was applied from either two or four points at the circumference of the tank and flooding rapidly effected. Excellent extractions were made with these plants and the resulting profits gave adequate return on the investment. Many difficulties were experienced, as I have indicated, at the start. The principal troubles were due to the acid salts of iron causing a high cyanide consumption and the difficulty of percolation through the high percentage of slime. The initial high consumption of cyanide rapidly fell to small amounts and there are nstances of practice in Australia where a consumption of only four ounces of potassium cyanide per ton treated is recorded. Even at this late date, no better examples of extractions are given than some of those made on the accumulated tailing piles in the State of Victoria.

I wish to refer again to mining methods further to illustrate the effect on treatment in the State of Victoria and other places. I know of no better illustration for this purpose than mining on the Eastern Australian quartz veins. The conditions that prevailed there, namely, the high efficiency of the mine labour and the length of time before more modern machine methods were introduced in underground work had profound effect on the actual ore treatment. The manager watched stoping operations closely and the ore was always broken clean, as little as possible of unprofitable vein matter or wall rock being broken or mixed with the ore. Generally the ore was broken and cleaned out of the stope and then filling put in and stoping again continued; the ore going to the mill was handled carefully at all points on the way. The actual breaking of the ore was carefully regulated by frequent pannings from the faces; little or no assaying was done. As a rule, the manager was successful in delivering to his mill a very clean ore of fair gold tenor and the free milling nature of the ore resulted in high development of stamp battery amalgamation. I know of no place where so much efficiency is obtained from amalgamation behind a stamp battery as in the State of Victoria. The tonnage milled was also reasonably high. Having an ore readily amenable to amalgamation and much care being given in mining and amalgamation to this ore, we find that of all the ore mined in the State of Victoria the greater bulk of it made such a low-grade tailing that it proved unprofitable to re-treat it by any process. To-day the immense accumulated tailings of Ballarat and Bendigo stand as lasting testimony to the efficacy of the treatment throughout. The principal aim of the miner there was to extract as much as possible of the metal from his ore and not to regard tonnage as so vitally important.

Since air compression, machine drilling and, improved stoping methods were introduced, the same care in breaking ore has not been given. Indeed, it is not possible to break ore as clean by machine as it is by hand. On the contrary, methods of milling and of crushing and subsequent for metal extraction have advanced and progressed in such a way (so to speak) as to counterbalance the dilution of ore by hastier stoping. "Dirty" ore is to-day largely counterbalanced by the rapid and cheap ways we have for conveying and moving ore in the mine, around the mine, and through the mill. Modern mills are more concerned with handling tonnage cheaply. The old mill was erected to dress well. The new mill is designed to work quickly. We are now enabled, by chemical and mechanical progress, to dress both quickly and well. It is, therefore, really the progress in modern ore treatment that has made it possible to mine quickly and cheaply, simply because we are able to extract the metals cheaply and well, and dilution of grade between limits becomes less vital than formerly. The best example that can be given in proof of this is to take the records of progress of the camp of Kalgoorlie and the camp of Cripple Creek, Colorado, where refractory telluride bearing ores are being handled at a remarkably low cost with splendid results. Moreover, this progress is not stationary, but each year shows a great advancement on the methods of the year prior. Kalgoorlie is now treating profitably ore that has a gold tenor of only $6.00 to $7.00 per ton. Another splendid example of practice is Mexico. Mexico is awakening—not because new mines are being found, but because the mines of a decade ago were worked to the point where hand methods were no longer profitable. Side by side in Mexico, we have mines, some of which savour of antiquity and other which are examples of the most progressive methods in gold or gold-silver mining in the world of to-day. Mexican mining has been vitalized by electricity, belt conveyance of ore, Kalgoorlie methods of treatment and American methods of mining.

It is only during the last ten or fifteen years that mining engineers as a body have become cosmopolitan, moving actively around the world, exchanging ideas, adopting and varying the practice of different countries for different situations. We must realize that on mining section usually develops one thing well and to get the best of everything we must adopt ideas from the different practices of different countries. I think this development is best shown in the gold mines of South Africa and the gold-silver mines of Mexico.

A note of warning should be sounded here. We can be too progressive without experience. Engineers will adopt or try to adopt the newest practice for a budding proposition, not having experience or familiarity with all branches of that practice. The result is frequently a costly experiment. Time and money will rectify the blunders of this unbaked maturity. Meanwhile, some of the mine's ore reserves are wasted.

A relation between mining and metallurgy that is becoming more appreciated is the proper mixture of the ore prior to treatment. I remember a mine, twelve years ago, at which stamp milling was followed by amalgamation, and subsequent treatment of the sand and slime by cyanidation was practiced. The ore was quartz carrying gold and a small percentages of iron pyrites. In the ore shoot (pitching at a low angle through the vein) was a streak higher in sulphides than the remainder of the body. This streak carried a little bismuth as carbonate. In the early operation of the mine little attention was paid to this streak and the ore was sent to the mill without regard to it. On some days ore carrying a comparatively large percentage of bismuth was milled, and then probably for several days no bismuth would be encountered. The result of this practice was that the bismuth, being a mineral of high specific gravity, clung to the plates, affected the amalgamation, and bothered the cyanide treatment. By properly mixing the ore, however, and keeping the amount from the sulphite streak as regular as possible, the mill men knew exactly the conditions confronting them and extractions were much improved.

An important feature of the relation between mining and milling is that of ore reserves to the capacity of the reduction plant. More failures are made in gold mining through too much and too early construction than from any other cause. It is necessary, for proper mining, that the construction-metallurgist should be in a position to check and verify ore reserves before plant design and erection. This factor controls the size of the plant for the developed ore.

However, a more important relation between mining and milling is that of life-expectancy. It is here that the highest skill of the engineers and managers is called into play. Most operators to-day, and all engineers, realize that to establish ore reserves and have a knowledge of future possibilities is of the very highest importance before designing and erecting a treatment plant. In many places and in a large number of important mines there is an interfering influence between mining and milling observable. I refer to the independent departmental management of a number of properties. It is highly important to have defined and properly correlated departments, each working systematically under the direction of a competent manager or engineer, but it is the height of absurdity to make such departments self-operative. Examples of this practice could be multiplied. Its effect can be more concisely realized by pointing to a few interfering factors.

We will suppose that we are dealing with a refractory ore which calls for cyanide treatment for the recovery of values, and we will suppose that there are interfering minerals, as for instance, maganese, bismuth, iron and copper salts irregularly distributed through the orebody. The metallurgist knows perfectly well that by proper selection of his ore he can cause beneficent reactions to take place during the treatment which will assist and render his operation more satisfactory and less costly. If such a mine were being operated on the departmental plan, the underground manager would have little regard for the work of the metallurgist but would conduct his operations to show to the best advantage for himself. The metallurgical end of the venture would probably prove costly, extractions would no doubt be low and irregular. Again should concentration be one stage in the treatment that is adopted, with the sensitive machinery now employed more labour would be required to control and regulate the machine due to the variation of mineral content. This would result in higher costs, lower extractions or both. Should mechanical difficulties to experienced in the mill and the underground department desire to show a greater tonnage and low cost, the mill would be handling more ore than should be properly treated and the metallurgical end would again appear at a disadvantage. It is needless to illustrate this further. The idea is apparent. We realize today that the best results can only be achieved on large propositions by departmental management working in perfect harmony through an executive engineering head. After all, this is the chief function of a high-class manager.

I cannot do better than conclude this brief review by giving the substance of what I had written two years ago. Metallurgy may be defined as the art of extracting metals from their ores and preparing them for the use of the manufacturer. It will, therefore, be understood that there is no plant or part of the equipment upon the surface of a mine that is not directly or indirectly connected with ore reduction. It should be understood that the surface equipment cannot be divorced from the mine equipment, and, therefore, the cost relationship between mining and metallurgy is the most important relationship of all because it is upon proper methods of cost keeping and distribution of charges that we are enabled to affect improvement and guide the operations of the mine. It will be recognized that it is impossible, in many cases, to separate absolutely the costs in one department from their bearing on the costs of some other department. Again, there is a close relationship between mining and metallurgy on the operating record sheets that are used to direct and control different departments. While we can benefit by the experiments of other countries, we can only use them as a basis of our own work

If an individual undertook the manufacture of shoes it is hardly likely that he would begin the process until he had obtained competent workmen. Why, therefore, should those incompetent to mine and treat ores undertake the extraction and reduction of these metals? It is clearly a matter for experts. Imitation has never fully solved any problem and never will. We must largely replace imitation in our practice and business methods by experience, and only take what, in the judgment of men trained in the business of mining, is thought to be suitable for the problem in hand. It must be realized, that every mine, no matter where situated, has its local conditions and local requirements and it is only by skill that these requirements can be successfully met. Every mine and metallurgical problem is distinct and depends upon the individual ore and on the particular chemical and physical characteristics of this ore. While the general design and mode of operations of any reduction works may be to all appearances similar to the mill adjoining, the operating metallurgist will have to use his brains to meet local requirements in his daily manipulation inside of the mill.

We have arrived at a state of mine equipment that would astound the forty-niner and we are triumphantly marching to a metallurgical goal that a few years ago was not contemplated. We are evolving the continuous treatment process, and few yet realize what this means for the future. An ideal process would be one which could treat ore without men and without supplies. We have not eliminated all the men yet, but they have been reduced over 50 per cent. in the past ten years. The consumption of supplies also has correspondingly diminished. There is no doubt that the matallurgical chemist will succeed in further reducing the present consumption of material.

In this brief review it is impossible to allude specifically to the splendid work that has been done in the various modifications of the cyanide process, and to enumerate and describe the different appliances that have been brought together to affect this evolution. It is unnecessary to describe the mining systems in use throughout the world for the extraction of gold ores, but the time is not far distant when we will have done with the stamp mill and all machines depending on the close application of an individual for their successful operation. We will simplify mills as we have simplified and improved underground systems. We will treat ore more cheaply than now, with fewer wheels and with less complication. Only recently we have witnessed the application of machinery to underground systems, the improvement of stoping methods, and the elimination of much physical drudgery. The wet treatment of refractory ores has been successfully accomplished. We are now facing simplification of plant design.

# THE OCCURRENCE OF PYRITES IN CANADA

Notes from the Report* of Dr. Alfred W. G. Wilson.

## PYRITES IN THE MARITIME PROVINCES.

Provincial reports and the reports of the Geological Survey of Canada contain many references to occurrences of the mineral pyrites in various localities in the provinces of Nova Scotia and New Brunswick. The writer has not been able to find any record of the mining of pyrites on a commercial scale at any locality in either of these provinces. In a few instances sample shipments have been made, but these were made many years ago, and the ore was valued for its copper content only.

The pyrites occurrences in the province of Nova Scotia, so far as the writer is aware, are not known to be large enough to be of commercial importance.

In the Province of New Brunswick, in the parishes of St. Stephen and St. David there are a number of localities in which both pyrites and pyrrhotite occur. No detailed description of these deposits appear to be available. Dr. Matthew, reporting on the district in 1876, states that they may be of commercial importance in the future. A verbal communication to the writer by a resident of St. Stephen confirmed this view. Exploratory work is needed to determine if any of those deposits are of commercial importance.

When visiting some supposed occurrences of copper ores in New Brunswick, the writer was informed that a large deposit of pyrites was known to occur on the northwest Mirmichi river above Red Bank. Direct inquiries of the alleged owners have elicited the information that no such occurrence is known to them.

In conclusion, it may be said that geologically one would expect that pyrites deposits would occur in certain localities in these provinces, since the conditions are very similar to those which prevail in Newfoundland and in several of the States to the south and west where these ores are mined. Much of the country is very difficult to prospect on account of the cover of loose waste, and so little is known of the country that it should not be said that such deposits do not occur. The most that can be said is that at present no deposits have been discovered and sufficiently exploited to show that pyrites ore can be obtained on a commercial scale.

## PYRITES IN QUEBEC.

The pyrites deposits of the province of Quebec have been, until recently, the most important known to occur in Canada. Many of the ore bodies which have been mined for pyrites were discovered during the decade 1860-1870. The first claims were located as gold prospects: subsequently development showed that the ore contained an important amount of copper, and the claims were therefore operated as copper properties. A little later it was found that the high sulphur content of these ores rendered them valuable for acid making. The total output of the province during the last thirty-five years has probably exceeded one million tons of ore carrying 40 per cent. of sulphur or more.†

At the present time there are only two properties in active operation. These are the Eustis, formerly the Crown mine, located about 7 miles south of Sherbrooke, and the McDonald mine located about 7 miles from Weedon station on the Quebec Central Railway. The property adjacent to the Eustis mine, the Capelton mines of the Nichols Chemical Company, was operated between the years 1863-1908. In addition, a considerable amount of pyrites was mined at the Howard mine, formerly the Cillis, and at Moulton Hill northeast of Sherbrooke. Important deposits of pyrites are known to occur at the King mine, adjacent to the Howard, and on a property near lake Coulombre north of Garthby station on the Quebec Central Railway. Brief descriptions of these properties are given in subsequent paragraphs.

The occurrence of copper sulphides and of pyrite has been reported from a number of other localities in the province of Quebec. Where exploratory work has been undertaken it has almost invariably been for the purpose of discovering copper or gold ores. Occurrences of this type are particularly numerous in the belt of altered igneous rocks which runs in a southwesterly direction past the city of Sherbrooke. The district for about ten miles northeast of Sherbrooke and for about the same distance towards the southwest is worthy of very careful exploration, especially in the neighborhood of some of the old prospect openings. As the available information with respect to these prospects relates rather to their possibilities as sources of copper ore, detailed descriptions are reserved for the report on the Copper Resources of Canada.

Copper bearing pyrites minerals occur on almost every lot of the eighth and ninth ranges of the township of Ascot, south of Sherbrooke. A number of prospects also occur on the eleventh range and there are scattered prospects on other ranges.

Eustis mine.—This property is located on lots 2 and 3, Concession IX, township of Ascot, about seven miles south of the city of Sherbrooke. It is owned and operated by the Eustis Mining Co.‡

The discovery, which was made about 1865, was located on lot 4 of the ninth range. The ore body was followed down from the outcrop, and the main mass of ore was found to occur on the lot to the south. The ore body consisted of a series of sulphide lenses, dipping approximately at an angle of 35 deg. towards the southeast. The bottom of the present shaft is about 3,200 feet below the old sills. The largest of the lenses was nearly 800 ft. in length along the dip; the horizontal width, parallel to the strike of the rock structures, varies to about 250 feet, while the thickness varies from a few inches to over 70 feet at the widest points. The other lenses were of the same general shape, though somewhat smaller.

The total output of the mine, since it was opened, has probably been in excess of half a million tons of ore. At present, development work is well in advance of mining and there is said to be more than two years' supply ready for stoping. The ore is a particularly pure pyrites with which is associated chalcopyrite. The shipping ore contains 40-45 per cent. sulphur, some of the lump ore occasionally running as high as 50 per cent. sulphur. It usually contains less than 2 per cent. of copper, and very small values in gold and in silver. The ore from the upper portion of the mine is said to have contained a higher percentage of copper.

The ore is free from arsenic and is an excellent ore for acid making. It is said that ore from this mine was the first pyrites used in America for making sulphuric acid. It is also probable that it will be found very suitable for sulphite pulp manufacture.

The mine is operated by electric power generated on the Coaticook river. It is also provided with an auxiliary steam plant to operate the mill at times of low water.

There is a dressing mill on the property equipped to treat about one hundred tons of ore per day. The flow sheet of the mill is given on page 36 of this report.

*Dressing and Uses.—By Dr. A. W. G. Wilson, Mines Branch, Ottawa.

Flow diagram, mill of St. Lawrence Pyrites Company

The dumps of waste which have accumulated during the earlier mining operations contain much good ore. They are now being sorted over and the concentrating ore is being sent to the mill for treatment.

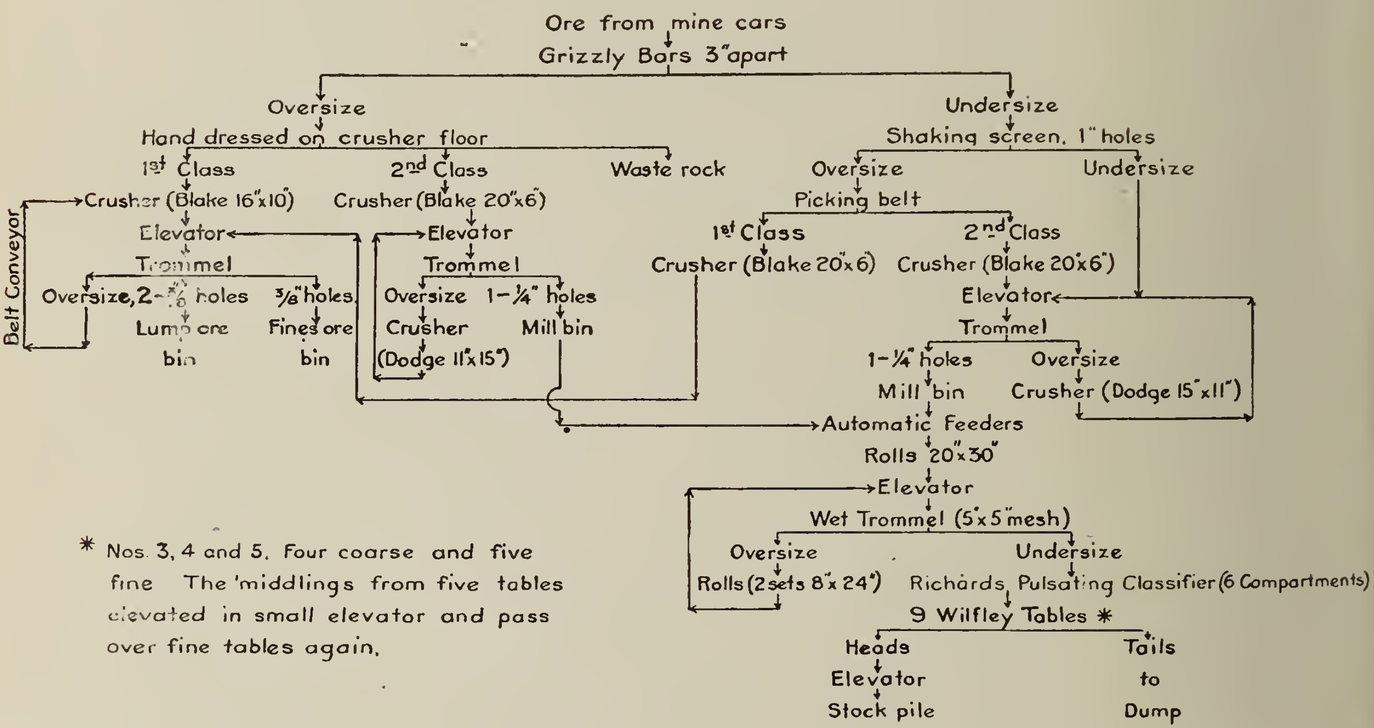
A small portion of the Eustis ore is utilized at the chemical works at Capelton. The greater part of the ore is shipped out of Canada to various chemical works in the United States. The copper and other values in the ore are recovered from the cinder at the smelter at Norfolk, Virginia, belonging to the principal owners of the Eustis company.

McDonald mine.—This property is located on lot 22, range I, township of Weedon, about 7 miles south and east of Weedon station on the Quebec Central Railway.

Exploration work was begun in the summer of 1909, by the sinking of small prospecting shafts. The preliminary work showed the existence of a promising body of ore, and more extensive operations were begun, including the sinking of what is now the number one shaft. During the last two years, development and exploration has been carried on systematically, and a considerable tonnage of ore carrying about 5 per cent. copper in addition to the sulphur has been shipped.

There are now two shafts on the property, number one, having a depth of 110 feet, and number two, which in January (1912) had a depth of 260 feet. The total amount of drifting, in January, 1912, was 900 feet, all

FLOW SHEET, MILL OF EUSTIS MINING COMPANY



had been done to block out ore in preparation for stoping. The development work is regarded as having proved the ore body to a depth of 300 feet, and for a distance along the strike of 530 feet. Development work is still being pressed forward, sinking at the rate of about 35 feet per month, and drifting at the rate of 100 feet per month.

The mine is now equipped with a boiler plant having a total capacity of 200 h.p. The air compressor plant is capable of supplying 600 cubic feet of free air per minute. In addition, each shaft is supplied with hoists, that at number two shaft having a capacity of 20 h.p.

An aerial tramway is now being installed to transport the ore from the mine to loading bins at the railway.

At present most of the ore is shipped to the works of the Nichols Chemical Company at Capelton. Smaller shipments have been made to United States points.
in ore. In addition a considerable amount of upraising

The property is operated by the East Canada Smelting Company, Limited.§

Capelton Mines.—The group of mines which may collectively be named the Capelton mines are located on lots 3 and 4, range VIII, township of Ascot. The original mines were Albert mine on lot 3, range VIII, and the Capel mine on the s.e. ¼ of lot 4, range VIII. With this group should also be included the old Crown mine on lot 4, range IX. As indicated in the reference to the Eustis mine, the ore bodies, first discovered on the Crown property, extend across the boundary towards the southeast, and it is on these ore bodies that the Eustis company is operating.

The first discoveries were made on the Capelton properties about 1863. They were first exploited as gold prospects, but development work soon demonstrated that there was a considerable quantity of cupiferous pyrite available. In the early days of their operation unsuccessful attempts were made to extract the copper by the Henderson process, and the mines were closed. Subsequently the properties passed into the control of G. H. Nichols & Co. This firm at first shipped most of the ore to sulphuric acid works near New York. Subsequently large acid works were established at Capelton, and later a small smelting plant, to treat the richer copper ores and cinder.

The mines were operated, practically continuously for about thirty years, and were finally closed in 1908, the deepest shaft having reach a depth of about 1,800 feet.

Several ore bodies occurred on the property on a strike approximately northeast, all having an inclination towards the southeast. The ore bodies varied in dimensions; in general the form appears to have been lenticular. The width of the several ore bodies varied considerably from narrow vein-like bodies to masses over 50 feet across. A considerable portion of the ore carried over 5 per cent. copper, and on one occasion an ore body of considerable size containing over 15 per cent. copper was encountered.

§President Chas. E. Force, 49 Wall St., N.Y.

The deposits on the Capelton properties are doubtless associated with big deposit of cupiferous pyrites on the Eustis property. They appear, however, to have carried more copper and to have been more irregular in their distribution.

The known ore bodies appear to have been exhausted and the mines were closed down in 1908. The closing of the mines is said to have been due chiefly to the difficulty of handling the water. Much of the plant has since been removed.

### PYRITES IN ONTARIO.

#### Brockville District.

Brockville Chemical Company.—In 1868, John Cowan and J. B. I. Robertson began mining for pyrite on lot 19, concession II, Elizabethtown township, Leeds county. The pyrite occurred in a series of lenses conformable to the lamination of a highly foliated pink granite gneiss. A series of irregular cavities and iron pyrites in parallel bands, and mining took the form of gouging out the richer shoots of ore, irrespective of any other consideration. No timbering was done, and when a part of the pit became unsafe, work at that point was abandoned. The main pit was sunk to a depth of 250 feet. The strike of the deposits was northeast, and the dip to the southeast. Mining operations ceased in 1879.

The ore from this property was used for making sulphuric acid in Brockville. After the mine was closed, pyrites was obtained from near DeKalb junction in New Hampshire. In a report of the Geological Survey of Canada,¶ the acid works are thus described:

"The Brockville Chemical Company's mine in the township of Elizabethtown has been closed since 1879. The chemical works are, however, still in operation. The pyrite at present used by the company is being brought from New Hampshire at the rate of a carload a day. There are 16 kilns in operation each having a capacity for 300 pounds of ore. The kilns are charged every hour and produce about 85 carboys of sulphuric acid a day. In the distillery there are 21 glass retorts attached to glass receivers for redistilling the crude acid. Besides the above, about 15 carboys of nitric and hydrochloric acid can be produced per day. In this case iron retorts and earthen receivers are used. The company employ 26 men."

A portion of the sulphuric acid was used at a fertilizer works in Brockville. Mixed acid was also supplied to two dynamite works in that neighborhood. One of these was started by C. W. Volney, the inventor of the Volney blasting powders, who afterwards sold out to one Griffin; and the other by Smith and Nelson, who were succeeded by Abbott and Harrison. Operations of all kinds ceased in 1880, and to-day not a vestige of these industries remains.

The cause of the decline and obliteration of these, at one time, flourishing industries was the prohibitive price of raw material. To the cost of mining near DeKalb Junction must be added hauling to the railroad and loading, freight to Ogdensburg, unloading re-loading on wagons and hauling three miles to the acid works. Working on imported ore, the plant could not successfully meet competitors. The evidence of men who worked in the old pits is to the effect that they were never completely exhausted.

McIlwraith Mine.—Lot 5, Concession IV, Darling township, Lanark county. The vein strikes slightly north of east along a contact between diorite on the south and crystalline limestone on the north. It was first opened up many years ago by W. H. Wylie, of Almonte, and Wm. Hall, of Darling, when prospecting for gold. They sank a shaft to a depth of 35 feet. The Nichols Chemical Company instituted mining operations under an option in September, 1899. The old shaft was deepened to 75 feet and from the bottom a drift run 8 feet to the east. A tunnel 150 feet long, with an outside approach of 50 feet was driven along the strike of the vein. This discloses a length of over 90 feet of workable ore, clean high grade pyrite enclosing lenses of quartz. A cross cut of 12 feet to the south failed to pierce the width of the deposit. The lens dips to the south at an angle of 60 deg., and pitches to the east away from the shaft which passed through it. It is claimed that it was caught again by the drift at a lower level. Work ceased at the expiration of the option, the end of April, 1900. Three carloads of ore were shipped. The mining was all done by hand. The gossan cap is 14 feet deep.

In a line of weakness caused by the contact of the diorite with the crystalline limestone, pyrite-bearing solutions have eaten out cavities and lenses in the limestone, depositing in them, pyrite and quartz. These break quite freely from each other, and the only impurity in the pyrite is small intermixed particles of quartz. Allowing for reasonable culling, an average sample from the tunnel, assayed by A. G. Burrows, yielded 42.6 per cent. sulphur, and a sample from a dump of 300 tons removed from the property to an adjoining lot, and which had been exposed to weather for six years, yielded 38.86 per cent. sulphur.

¶C. G. S., 1883, Part L, p. 10.

(To be continued.)

# SPECIAL CORRESPONDENCE

## NOVA SCOTIA

**Dominion Coal Outputs.**—The production from the Glace Bay mines in February was not so large as expected, owing to a severe snow-storm and "silver thaw" towards the end of the month. The sleet deposit was the worst for very many years, and completely demoralized all telephone and telegraph communication. About thirty thousand tons of possible output were lost through this storm. The actual outputs for February were, from the Glace Bay mines 336,919 tons and from the Springhill mines 32,155 tons. In March the Glace Bay production will probably be 370,000 tons and the Springhill production 36,000 tons. The net increase for all the Coal Company's mines in the first three months of 1913, as compared with the same period of 1912, will be about 118,000 tons.

Shipping was continued at Sydney until the 17th of February, and, if the drift-ice conditions are favourabel, should recommence towards the end of March. It is quite possible that shipping to St. Lawrence ports may commence about the fifteenth of April, as the ice in the river is not heavy this spring. Indications are that the Cape Breton collieries will ship an unusually large amount of coal to St. Lawrence ports during the coming summer.

Nothing in the progress of the mining industry in Cape Breton is more striking than the changed conditions regarding the working of the collieries in the winter months. The Dominion Coal Company's output for the first quarter of 1913 will be about 1,090,000 tons, which exceeds by 264,000 tons the entire output for the year 1893, the year in which the Coal Company was formed. In 1893 the output for the first quarter was 75,000 tons, whereas in 1913 a single week's production will reach 100,000 tons.

It is perhaps worth while to mention that in March 1913 the Dominion Coal Company will have been incorporated twenty years. In 1893 the output was 826,000 tons for the year. In 1912 the output was 4,513.269 tons, and No. 2 Colliery alone produced a tonnage equal to the entire output of the Company in the year of its incorporation. It is within the probabilities that the 1913 output will reach 4,900,000 tons, in which case the Company will, in twenty years, have increased its production six-fold. It can be safely stated that the Dominion Coal Company is the largest and most important single asset in Nova Scotia, and its prosperity and that of the Province are one and the same.

**Cape Breton Coal, Iron & Railway Company.**—It is understood that negotiations have been proceeding between this company and the Dominion Coal Company which may enable the Cape Breton Company to recommence operations. It may be remembered that this company opened and equipped a colliery at Broughton, but selected a site for the slopes which rendered it necessary to cross an area owned by the Dominion Coal Company before it was possible to win the main areas of the Cape Breton Company. In the past it was not found possible to come to an arrangement, but it is now probable that the Cape Breton Company will be able to obtain a lease from the Dominion Coal Company, which will enable them to proceed with the sinking of the deeps, and to mine coal. The deeps were sunk as far as the boundary of the Coal Company's property, but work was discontinued about 1907 owing to the impossibility of the deeps proceeding further without trespassing on the Coal Company's areas.

It is further stated that the Nova Scotia Steel & Coal Company may obtain permission from the Dominion Coal Company to mine coal from submarine areas off Sydney Mines belonging to the Dominion Company and adjoining the present undersea workings of the Scotia Company.

# ONTARIO

## COBALT, SOUTH LORRAIN, GOWGANDA AND ELK LAKE.

**Casey Cobalt.**—The Casey Cobalt Mining Company went on a regular production basis the week ending March 22nd. The weekly production will amount to 16,000 ounces, of which 6,000 ounces, or enough to make current expenses and leave a profit, will come from the mill as it is at present constitued. When it is treating 50 tons per day instead of its present 25 tons, this will of course be increased in proportion. The duplication of the mill should now not be a matter of any great length of time as all the machinery has been hauled over the clay roads and construction can go ahead rapidly.

As an example of success attained by perseverance under disappointment and difficulties the history of the Casey is illuminating. Situated eight miles out in the clay belt ,where no previous successes had blazed the way the company operated four years without making a cent of profit. The Casey had not the prestige that belongs to the Cobalt camp to help it and transportation difficulties consisting in the haulage over eight miles of bad roads to an island of conglomerate rock in a sea of clay was not calculated to inspire optimism. Patches of high grade ore were discovered and taken out, but nothing of importance was discovered until two years ago when the No. 6, or big vein of the mine, was cut.

It seems most probable that the conglomerate ridge on which the Casey is situated was at one time an island standing out above an arm of Lake Temiskaming. In the swamp below the mine a diamond drill was put down 210 feet before striking rock and close to the mine it had to be sunk over 90 feet before the bottom of the clay was found. The conglomerate ridge is about three miles running from the Casey Mountain where the granite contact occurs to the point where the rock disappears under the heavy overburden of clay. With the exception of three or four claims all this ridge is owned by the English syndicate which put the Casey Cobalt Mining Company on the market. They have 25 claims of 40 acres each, or a thousand acres, which, in the light of developments on the Casey, would all appear to be well worthy of prospecting. Much of this assessment work on these claims is now being done with the diamond drill, not to discover veins, but to establish depth of formation.

Unlike the Cobalt camp, payable ore is not mined from the grass roots down. The No. 1 or Robber vein, as it was called by the old management, was strong and well defined at the 30 and 100-foot level, but there was not more than eight or nine ounces of silver to the ton in the smaltite and niccolite.

The first ore body of any length and size struck on the Casey was the No. 6 at the 210-foot level. It was intersected in a cross cut 150 feet long from the old workings on No. 1 and it is significant that it does not show at all one the surface. It has now been developed for 350 feet, all of high grade, as it is reckoned high grade in Cobalt, that is about 2,500 ounces to the ton. The first car taken out of this vein gave returns to the company of $132,000 and this is the grade of ore right along the shoot. The vein is sometimes from six to nine inches of high grade ore and sometimes it is split up into four or five stringers. It has been drifted upon across the line on to the Kismet property, and here it is as strong as in any place in the whole of the workings. No ore has been shipped from the Kismet yet, though some has been stoped, but as two of the best veins have been definitely followed on to this claim south of the Casey it would appear to be a good prospect.

From the 210-foot level of the No. 6 vein a raise was put up 64 feet in good high grade ore all the way. At the top of this raise there was a patch of lean ore, but after drifting 25 feet to the south of the No. 2 raise, it came in well again and promises to develop finely on this level. Below the 210 or main level on the No. 6 vein another level has been opened up at the 260-foot and here again high grade has been encountered and a fair body of ore can be reckoned on in the reserves, but in drifting to the north the Keewatin contact is reached and as in Cobalt values disappear when the conglomerate is left. A small shoot of high grade ore was mined in the keewatin, but as a general rule the same conditions apply as on the West Ridge at Cobalt, where exploration in the keewatin under the conglomerate has not proven at all remunerative. The average depth of the conglomerate in the Casey is about 250 feet from the collar of the old shaft, but as it dips to the south it will probably be considerably deeper on the Kismet. As in Cobalt the highest grade ore in the widest ore bodies is found close to the keewatin—conglomerate contact.

The success which attended the opening up of the No. 6 vein led to the further exploration of No. 1, and it is now to be credited with a good body of ore. A cross cut was driven from the end of the old workings at the 100-foot level and at a distance of 200 feet a 60-foot shoot of high-grade ore was developed. On the same vein ore has also been found at the 160-foot level near the south boundary and in a winze put down 24 feet at a point 200 feet north from the shaft milling ore has been discovered so that there is every possibility of blocking out a good length of milling ore with some patches of high grade. The milling ore runs about 40 ounces to the ton. There are other veins, but they have not received much development to date.

The Casey Cobalt consists of 120 acres altogether, two claims together and one on Sutton Bay, near Lake Temiskaming. The eastern of these two claims has not been developed at all and on the one property not more than three acres have been touched. The Kismet claim is being developed from the Casey. A shaft has been sunk on the Townsite Extension and one or two veins cut. This is all the work going on at present, development in this isolated section being confined absolutely at the present time to the Casey Cobalt and associate interests.

The new shaft should soon be completed, when many of the difficulties that have hitherto attended the raising of ore will be removed. It has been found that it is cheaper to pay the settlers $2.50 a cord to cut wood than to haul coal from New Liskeard, and there are probably 5,000 cords in the yards now, but this summer arrangements will probably be made whereby the fuel bill will be cut down very materially.

During the year 1912 the McKinley-Darragh produced 2,717,383 ounces of silver worth $1,621,010. The total net profits on operations were $1,153,848. The total cost per ounce was 18.59 cents, leaving a profit of 43.07 cents per ounce. The ore reserves now developed show a total of 152,800 tons, estimated to contain 5,368,500 ounces of silver, 100,400 tons from the McKinley containing 4,133,500 ounces, and 52,400 estimated to contain 1,235,000 at the Savage. This compares with 5,561,780 ounces in 1912. While 2,717,383 ounces were produced during the year, the ore reserves were increased by almost 200,000 ounces. After paying $1,123,646 (including the first of January disbursement) there was a surplus of $422,326.

**Lawson Progress.**—The Lawson has discovered another good ore shoot on the No. 8 vein at the 115-foot level. In a raise 270 feet from the No. 8 shaft, a shoot of very spectacular ore has been discovered and has been developed for some distance. Th ore will run from 5,000 to 10,000 ounces to the ton.

**High Grade on Temiskaming.**—At the 575-foot level of the Temiskaming mine there has now been developed a shoot of high-grade ore from 65 to 70 feet long, with prospects of its continuing for some distance. The vein is from three to four inches wide, of 2,500 ounce ore, and there appears good prospect of making a tonnage of milling rock in the wall rock. This is the first ore body of any length and size the Temiskaming has been able to develop in the diabase below the keewatin.

### PORCUPINE AND SWASTIKA.

**McEaneny Mill.**—The five-stamp mill at the McEaneny is making $500 a day, or enough to pay all current expenses and leave a good profit. Another five stamps will be installed almost at once, as accommodation has been left for them in the present building. For the first half of the present month the heads to the mill ran $35 to the ton on an average. As this first instalment of the mill was designed more as a sampling plant than as a revenue producer, the results obtained are regarded as highly satisfactory. Regular clean ups are being made, bullion will be shipper every month, the first consignment going out at the beginning of the month.

Development continues to be most gratifying The ore shoot at the 200-foot level is now 600 feet long. The south face is now five to six feet of ore, assaying $40 to the ton. All the ore going through the mill is coming from development or the dump.

**Lucky Cross.**—At a distance of about twelve feet from the shaft a cross cut has penetrated the No. 16 vein of the Lucky Cross mine at Swastika, at the 200-foot level. The vein looks promising. Most of the machinery has arrived for the new mill and it is expected that it will be running by the first of April. The mill at the Swastika mine is already in operation. At Kirkland Lake there is much prospecting activity and a good many claims have changed hands.

There has been a fresh outbreak of lawlessness at Porcupine very largely owing to the withdrawal of provincial police from the camp. Non-union men going to and fro between the towns and their work have been waylaid and manhandled. These occurrences became so frequent that the non-union men at the mines united and proceeded to reprisals. At Timmins, Mayor Wilson read the Riot Act when he heard that a clash was likely between the non-union men and the union men and the situation looked dangerous. Fifteen provincial constables have been rushed back into the camp and they should be able to cope with the situation. There are over a thousand men now working at the various mines and not more than 200 strikers still remain in the camp.

**Jupiter At Work.**—The Jupiter has started work again under its new mine manager, Mr. Little, Mr. R. W. Brigstocke remaining as consulting engineer. The Porcupine Gold Mines is now ready to start work again on the Vipond and nearly every company that had any pressing need to resume at once is developing again.

## BRITISH COLUMBIA

Generally, mining continues to make good progress in various parts of the province, the chief exception being at the coal mines on Vancouver Island, of the Canadian Collieries (Dunsmuir) Limited. However, this company is succeeding in operating its Comox colliery, with mines about Cumberland, and getting out a considerable tonnage of coal, though not as much as before the miners went on strike. No coal mining is yet being done at the company's Extension colliery mines, efforts being concentrated in keeping open those first above-mentioned. In Kootenay district the only present evidence of labor difficulty is that given by a strike of miners at the Queen gold mine, Sheep Creek camp, Nelson mining division. If it be the intention of the Western Federation of Miners to call its members out of Slocan mines following the adverse majority report of the Board of Conciliation that investigated the conditions in connection with the demand of the Union for an increase of 50 cents a day in the men's wages, there is not yet any indication of such intention. It has been reported that both the Granby and Hedley mining companies have reduced wages 25 cents a day, in accordance with their announced intention of doing so under the sliding scale arrangement made when the price of copper went up. It is significant that the Britannia Company, which the Western Federation is fighting, is continuing to pay the higher rate which it voluntarily gave its men last September. If it be true that the Granby and Hedley companies have reduced the men's wages the position is that the Britannia Company is still paying the high price copper rate, notwithstanding that it is entitled to lower the rate to the old scale in force before the price of copper went up.

**Slocan and Rossland.**—These districts are associated in this notice for the reason that some information follows relative to the Le Roi No. 2, Ltd., and the Van-Roi Mining Co., the latter being an auxiliary company of the former.

The report of the Van-Roi Mining Co. for its last fiscal year shows that of 4,488 ft. of development work done, 3,470 feet was drifting and cross-cutting, and 1,018 ft. raising and sinking. The average cost of this work was $8.91 per foot. The quantity of ore concentrated was 54,115 tons, assay returns of which showed average valuable metal contents to have been 15.02 oz. silver per ton, 3.66 per cent. lead, and 6.26 per cent. zinc. The mill products were: Lead concentrate, 2,392.5 tons, containing 179.75 oz. silver per ton, 60.2 per cent. lead, and 11.1 per cent. zinc; and zinc concentrate, 2,570.5 tons, containing 60.8 oz. silver per ton, 3.7 per cent. lead, and 45.1 per cent. zinc. The total metal contents of the 4,963 tons of concentrates were: Silver, 556.363 oz.; lead, 3,070,640 lbs.; zinc, 2,848,860 lbs. In addition there was 712 oz. of silver, 1,860 lbs. of lead, and 3,000 lb. of zinc in six tons of ore shipped crude. The cost of mining the ore was $2.58 per ton, which was a little higher than that of the immediately preceding fiscal year. Cost of concentrating was 95 cents a ton. The Van-Roi mine and mill are situated within half a dozen miles of Silverton, Slocan Lake.

The annual report of Le Roi No. 2, Limited, owning the Josie, No. 1, and other properties in Rossland camp, shows that during the company's last fiscal year development work consisted of 5,817 feet of drifting and cross-cutting, and 298 feet of raising and sinking; total 6,115 feet. The quantity of ore mined was 40,112 tons, of which 18,257 tons was shipped crude to the Trail smeltery, and 17,116 tons was concentrated, the latter yielding 1,659 tons of concentrate. Assay returns showed that the ore shipped contained 0.7754 ounces gold and 0.6727 ounces silver per ton, and 1.39 per cent. copper. The concentrate contained 1.096 ounces gold and 0.643 ounces silver per ton, and 1.14 per cent. copper. Average value of the ore was $20.10 per ton, as compared with an average of $21.08 per ton for 27,098 tons shipped in the previous year. Concentrate averaged $25.75 per ton. Mining costs appear to have been $3.46 per ton, and smelting charges $5.77; while development charges and deduction for depreciation together come to $2.95 per ton; total per ton, $12.18, as compared with $11.41 for the preceding fiscal year. By arrangement with the Consolidated Company, boundaries between the respective properties of the two companies were adjusted, extra-lateral rights relinquished, and all claims for trespass, etc., waived.

At the meeting of the Le Roi No. 2, Limited, held in London during February, in the course of his address to shareholders, the chairman said: "One of the pleasantest features of the present Le Roi No. 2 position is the success which has attended the Van-Roi mine during the past year. That mine shows a net profit of £27,000 odd, and, though the last few months' workings have been disappointing, there is not the slightest doubt that this is only temporary, and due to causes easily explained, and that we may now safely regard the Van Roi as a profit-earner and a dividend-payer. It looks, indeed, as though the situation which was originally anticipated is about to be realized, namely, that when the Le Roi No. 2 production may be temporarily at a low ebb its receipts should be kept up by dividends from the Van-Roi mine. This is exactly what would have been the case at the present moment, had not the Van-Roi profits to go to pay off the capital debt which the mine had contracted."

**Coast District.**—The most important recent occurrences in connection with metalliferous mining in the Coast district have been those that resulted in the calling out, by the Western Federation of Miners, of between 600 and 700 men who had been employed by the Britannia Mining and Smelting Company, at its copper mines, concentrating mill, and auxiliary works, at and near Britannia Beach, Howe Sound. This action on the part of the miners' union had been threatened for some time, although it was hardly expected it would take place until several weeks later. The position was that last year a Board of Conciliation and Investigation having been held, a majority report recommended that the company withdraw its refusal to permit union officials to visit its mines to collect union dues, hold meetings, etc. The representative of the company on the board did not subscribe to the majority report, nor has the company since yielded on the point. The situation is an unusual one, for the company owns a large area of land surrounding its mines, together with the camp sites, all buildings, boarding and bunkhouses, landing dock, foreshore, etc. For some time it permitted union representatives to visit its camps, but eventually, concluding that (notwithstanding that there were not any complaints concerning working conditions, rates of wages, accommodation, etc.) this concession was being made use of to the detriment of its own interests, it forbade such visits and the holding of union meetings in any of its buildings. In support of its action it is claimed by its representatives that the company having done everything in reason for the comfort, and even for the recreation of its employees, it is well within its rights in the stand it has taken and is maintaining. In addition, it is urged that it has even gone farther than most other mining companies in expending money for the benefit of its employees, who, consequently, have no reasonable cause for complaint. It is a fact that for a long while those who financed the company found its operations a heavy drain at a time of monetary stress in the United States, where the chief owners reside. Well on for $1,500,000 was advanced to the company by Mr. Grant B. Schley, of New York, and his associates to carry out the work of development to explore the mine, and this was in addition to much money that earlier had been spent on similar work. The direct result of the enterprise of Mr. Schley and associates was that much ore of a payable grade was found, and production became important. In 1911, there was mined nearly 119,000 tons of ore, containing 46,000 ounces of silver and 8,685,000 pounds of copper; while in 1912 the output of ore was increased to 193,000 tons, containing between 70,000 and 80,000 ounces of silver and between 14,000,000 and 15,000,000 pounds of copper. For some time past 60 to 700 men have been employed by the company, and the daily outlay in wages and materials, including construction and substantial additions to plant and equipment, was approximately $6,000 a day. No other metalliferous mining enterprise on the British Columbia coast has in recent years approached this, neither in magnitude nor results. Yet the Western Federation of Miners says, in effect, we will not allow you to spend your own money in your own way, not if we can prevent it. However, the management of the company is not to be deterred from its course and at the time of writing it is operating its concentrating mill 20 hours a day, with two over-time shifts of 10 hours each, instead of the customary three 8-hour shifts, and is running its three-and-a-half mile aerial tramway from the mines down to the concentrator under similar conditions, and getting down practically three-quarters of the usual quantity of ore, while at the mine two shifts of men are delivering the ore to the tramway. Besides this, the work of driving the 5,000-foot cross-cut tunnel, the object of which is to open the mine at much greater depth and allow of delivery of ore to the tramway at a point half-way down the mountain, and so expedite transportation to the mill, has been resumed.

## COMPANY NOTES

### NOVA SCOTIA STEEL AND COAL

The annual meeting of the Nova Scotia Steel & Coal Company shareholders, held at New Glasgow on March 26th, was well attended. In every phase of the work carried on in the different plants in the past year, the efforts have shown substantial increases. An assurance that a good year was in store was announced by President Harris, who said that the total steel output for the first half of the year had already been contracted for at an improved price. The coal output would be larger and the prices maintained, while from the ore mines they anticipated a record yield at splendid prices. Of the new work outlined for the year, a new open-hearth furnace would be installed at Sydney Mines, a new colliery opened there, and some new equipment installed at Wabana. The retiring board was re-elected.

### ASBESTOS CORPORATION.

The Asbestos Corporation of Canada held its first annual meeting recently, when reports for the seven months ended December 31st were read by the president, Mr. W. G. Ross. The old board was re-elected for the ensuing year, as follows: W. G. Ross, president; H. E. Mitchell, vice-president; C. W. Colby, H. J. Fuller, Uzal H. McCarter, Thos. McDougall and William McMaster.

### HOLLINGER'S LATEST.

Profits of the Hollinger Gold Mines from January 1st to February 25th, according to the regular four weekly report being sent out to-day, with dividend cheques, were $241,600. This added to the surplus brought forward from 1912, makes $593,402, less two dividends of $180,000, leaving a surplus of February 25th of $412,-402. In the four weeks ended February 25th hte mill ran 91 per cent. of the possible running time, treating a total of 9,240 tons, or an average of 330 tons per day.

## STATISTICS AND RETURNS

### LA ROSE FOR FEBRUARY.

La Rose's February statement shows a total production for the month of 230,102 ounces of a value of $136,-182. This, with sundry income of $2,330 for the month, brought the total up to $138,512. With cost of marketing and other expenses deducted, a balance of $81,103 was left for the month. The financial position of the company, on February 28th, showed cash on hand of $1,425,886, outstanding shipments of $184,032, and $78,017 in ore ready for shipment.

### COBALT ORE SHIPMENTS.

Shipments for the week ending March 15th were almost double the amount of the previous week and the bullion shipments were also away above the average. Altogether thirteen mines were represented on the list, but only two sent out more than one car of ore. These two being the Dominion Reduction, shipping concentrates, and Kerr Lake sending out one car of high-grade and one car of low-grade. Drummond shipped concentrates, Bailey Cobalt high-grade, Right of Way low-grade, and Chambers-Ferland low-grade.

The shipments for the week in pounds are:

| Mine. | High | Low | Lbs. |
|---|---|---|---|
| Nipissing | .. | 1 | 106,840 |
| Beaver | 1 | .. | 43,000 |
| Dominion Reduction | 2 | .. | 127,300 |
| Peterson Lake | 1 | .. | 81,000 |
| Townsite | 1 | .. | 66,100 |
| La Rose | 1 | .. | 70,500 |
| Drummond | 1 | .. | 61,479 |
| Bailey Cobalt | 1 | .. | 41,830 |
| Right of Way | .. | 1 | 63,278 |
| Chambers-Ferland | .. | 1 | 64,000 |
| Cobalt Lake | 1 | .. | 64,482 |
| McKinley | 1 | .. | 58,309 |
| Kerr Lake | 1 | 1 | 121,290 |
| | 11 | 4 | 969,708 |

The bullion shipments for the week were:

| Mine. | Bars. | Ounces. | Value. |
|---|---|---|---|
| Nipissing | 85 | 103,152.80 | $61,108.03 |
| Buffalo | 60 | 66,918.00 | 34,000.00 |
| Crown Reserve | 38 | 43,000.00 | 26,000.00 |
| Colonial | 1 | 635.00 | 374.00 |
| Dominion Reduction | 34 | 38,474.40 | 23,084.64 |
| | 218 | 252,180.20 | $144,566.67 |

### BRITISH COLUMBIA ORE SHIPMENTS.

For the year to date the total ore production is 570,-008 tons. Smelter receipts for the week ended March 22nd were 47,725 tons and for the year to date, 491,678 tons. Ore output and smelter receipts in detail:

Ingot brass, 11 to 15 cents per pound.

March 25.—(Quotations from Drummond, McCall & Co., Toronto):
Summerlee No. 1, $26.00 (f.o.b. Toronto).
Summerlee No. 2, $25.00 (f.o.b. Toronto).
Midland No. 1, $20.50 to $21.50 (f.o.b. Toronto).
Nidland No. 2, $20.50 to $21.50 (f.o.b. Toronto).

## GENERAL MARKETS.

Coal, anthracite, $5.50 to $6.75.
Coal, bituminous, $3.50 to $4.50 for 1¼ inch lump.

### Coke.

March 20.—Connellsville coke (f.o.b. ovens):
Furnace coke, prompt, $2.45 to $2.50 per ton.
Foundry coke, prompt, $3.00 to $3.50 per ton.

March 20.—Tin, Straits, 46.25 cents.
Copper, Prime Lake, 14.85 to 14.95 cents.
Electrolytic copper, 14.80 to 14.90 cents.
Copper wire, 16.00 to 16.25 cents.
Lead, 4.35 to 4.40 cents.
Spelter, 6.15 to 6.25 cents.
Sheet zinc (f.o.b. smelter), 8.25 cents.
Antimony, Cookson's, 9.00 cents.
Aluminium, 26.50 to 27.00 cents.
Nickel, 40.00 to 45.00 cents.
Platinum, ordinary, $46.00 per ounce.
Platinum, hard, $51.00 per ounce.
Bismuth, $2.00 to $2.25 per lb.
Quicksilver, $39.00 per 75-lb. flask.

# PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assaye Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

# DEPARTMENT OF MINES GEOLOGICAL SURVEY.

## PUBLICATIONS

**The Geological Survey has published maps and reports dealing with a large part of Canada, with many local areas and special subjects.**

A catalogue of publications will be sent free to any applicant. A single copy of a map or report that is specially desired will be sent to a Canadian applicant free of cost and to others at a nominal price. The applicant should state definitely the Precise area concerning which information is desired, and it is often of assistance in filling an order for a map or report if he states the use for which it is required.

Most of the older reports are out of print, but they may usually be found in public libraries, libraries of the Canadian Mining Institute, etc.

### REPORTS RECENTLY ISSUED:

**CANADA**

1085. Descriptive Sketch of the Geology and Economic Minerals of Canada. Accompanied by a geological and mineral map of Canada, by G. A. Young and R. W. Brock.
1218. Summary Report of the Geological Survey for 1911.

**NEW BRUNSWICK and NOVA SCOTIA**

1113. Memoir No. 16. The Clay and Shale Deposits of Nova Scotia and portions of New Brunswick, by H. Ries and J. Keele.
1165. Memoir No. 18. Bathurst District, New Brunswick, by G. A. Young. Maps not yet published.

**QUEBEC**

1110. Memoir No. 4. Geological reconnaissance along the line of the National Transcontinental Railway in Western Quebec, by W. J. Wilson, accompanied by a map.

**ONTARIO**

1213. Memoir No. 28. The Geology of Steeprock Lake, Ontario, by Andrew C. Lawson. Notes on Fossils from Limestone of Steeprock Lake, Ontario, by Charles D. Walcott.

**NORTH WEST PROVINCES**

1204. Memoir No. 24. Preliminary Report on the Clay and Shale Deposits of the Western Provinces, by Heinrich Ries and Joseph Keele.

**BRITISH COLUMBIA**

1121. Memoir No. 13. Southern Vancouver Island, by Charles H. Clapp.
1175. Memoir No. 21. The Geology and Ore Deposits of Phoenix, Boundary District, B.C., by O. E. LeRoy.

**YUKON AND NORTH WEST TERRITORIES**

1080. Report on a part of the North West Territories drained by the Winisk and Attawapiskat Rivers, by Wm. McInnes.
1228. Memoir No. 31. Wheaton District, Yukon Territory, by D. D. Cairnes. Maps not yet published.

### MAPS RECENTLY ISSUED:

**CANADA**

1042. Mineral Map of Canada. Scale 100 miles to 1 inch.

**NOVA SCOTIA**

1133. Map 13A. Kingsport sheet, Nova Scotia, No. 84. Scale 1 mile to 1 inch.

**NEW BRUNSWICK**

1181. Map 35A. Reconnaissance Map of Parts of Albert and Westmoreland Counties, N.B. Geology and topography. Scale 1 mile 1 inch.

**QUEBEC**

1178. Map 32A. Larder Lake and Opasatika Lake, Nipissing, Abitibi and Pontiac, Ontario and Quebec. Geological. Scale 2 miles to 1 inch.
1184. May 38A. Danville Mining District, Quebec. Geology. Scale 1 mile to 1 inch.

**ONTARIO**

964. Geological map of portions of the districts of Algoma and Thunder Bay, Ontario. Scale 8 miles to 1 inch. Second edition.
1177 Map 31A. Larder Lake, Nipissing District, Ontario. Geology. Scale 1 mile to 1 inch.

**ALBERTA**

1132. Map No. 7A. Bighorn Coal Area, Alberta, by G. Malloch. Scale 2 miles to 1 inch.

**BRITISH COLUMBIA**

792. West Kootenay sheet, B.C. Geological. Scale 4 miles to 1 inch.
1237. Map 62A. Nelson and vicinity, British Columbia. Geology and topography. Scale 1 mile to 1 inch.
1247. Map 69A. Route map of part of Nass River, British Columbia. Scale 8 miles to 1 inch.
1219. Map 54A. Nanaimo Coal Area, Vancouver Island, B.C. Scale 1½ miles to 1 inch. Contour interval 100 feet.

**YUKON and NORTH WEST TERRITORIES**

1089. Map 9A. Explored Routes on parts of the Albany, Severn and Winisk Rivers. Scale 8 miles to 1 inch.

NOTE.—Maps published within the last two years may be had, printed on linen, for field use. A charge of ten cents is made for maps on linen.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon. Letters and samples that are of a Departmental nature, addressed to the Director, may be mailed O.H.M.S. free of postage.

***Communications should be addressed to* THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.**

# BUYERS AND SELLERS OF METALS

# THE NEW McKIERNAN-TERRY CLASS A-C

## Self-Rotating Combination

# HAMMER DRILL

The only Heavy Hammer Drill

## THAT WILL NOT BREAK STEEL

Note the following points of interest :—

¶ There is a removable handle so that a telescope feed may be attached when using drill for stoping.

¶ The hollow lever handle, filled with oil which is fed by pressure through the top head of the machine, thus furnishing thorough lubrication.

¶ The phosphor bronze hose couplings of large diameter and standard threads, with a hose clamp locked on.

**THE VALVE THAT WILL NOT FREEZE.**

¶ The extra heavy side rods and side rod springs.

¶ The removable heavy Front Head, for sinking. This Front Head, may be removed and a light Front Head attached when using the drill for drifting or stoping.

¶ The Oil Plug for Oiling Front Head.

¶ The machine has either square or hexagon chuck for hollow steel.

¶ This machine will bottom a 12 ft. hole 1¼ in. in diameter in the hardest rock.

¶ The drill is self-rotating; all the operator has to do is to hold it. 100 ft. of holes per ten hour shift is easy for this machine.

## Siemens Electric Hoisting Engine supplied and installed by us for the Dominion Coal Co., Cape Breton

**Output 185 short tons per hour from a 5000 foot slope, peak load 1320 H.P.**

**We have supplied or on order for Canada the following Electric Hoisting Engines:**

1—1900 H.P. Peak Load, Dominion Coal Company.
1—1900 H.P. " " Dominion Coal Company.
1—1560 H.P. " " Canadian Collieries, British Columbia.
1—1320 H.P. " " Dominion Coal Co., (in operation).
1— 750 H.P. " " Canadian Collieries, British Columbia.
1— 400 H.P. " " Dominion Coal Co., (in operation).
1— 450 H.P. " " Acadia Coal Co., (in operation).
1— 450 H.P. " " Acadia Coal Co., (in operation).

The Siemens Companies undertake the complete electrical equipment of mines, collieries, factories, steel works, rolling mills, pulp and paper mills, and electrical plants of every description. Over 200 electrically driven hoisting engines have been installed with peak loads from 500 H.P. to 5000 H.P.

Further information will be gladly furnished on request, and schemes prepared showing the economy of electric drive over steam winding.

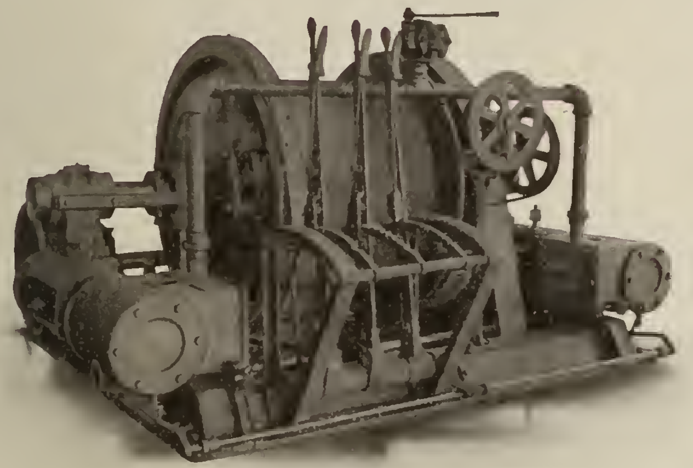
# HOISTING ENGINES

## STEAM AND ELECTRIC



**Standard Double Cylinder, Single Friction Drum, Reversible Engine with Dial Indicator.**

Your hoisting engine is one of the most important factors of your mine equipment. This element of your plant, which plays such a vital part in your monthly production, should be, above all things, *reliable.*

Now these rugged, amply proportioned Steam and Electric Hoists with *large* bearings, *powerful* band friction clutches and *broad* break bands *are most* reliable.

Friction and vibration are the two factors which in the use of a machine have no function except to wear it out and rack it to pieces. In these hoists friction is reduced to the limit by large anti-friction metal bearing surfaces and liberal provision for lubrication, Vibration is done away with by carefully proportioning all rotating and reciprocating parts.

The care bestowed upon all factors effecting the life and reliability of a hoist, qualifies these machines as the best, and the price is commensurate.

## The Cheapest Rooting

J-M Asbestos Roofing is lower in first cost than shingles, tin and slate and cheaper than *all* other roofings when cost per year is considered.

Tin, iron and most prepared roofings are a continual trouble and expense, for they require coating or regraveling every few years. No coating, gravel or other protection is *ever* needed for J-M Asbestos Roofing. *Its first cost is the only cost.*

# J-M Asbestos Roofing

consists of layer on layer of Asbestos (rock) Felt securely cemented together with Trinidad Lake Asphalt. This makes a ready roofing that is literally a pliable stone—with the everlasting qualities of stone. Sparks or burning brands cannot ignite it. Rain, snow, heat, cold, salt air or chemical fumes cannot injure it. This roofing is in good condition today on many buildings after more than a quarter-century of service. J-M Asbestos Roofing can be used on any type of building. Write our nearest Branch for a piece of the curious Asbestos Rock and illustrated Catalog No. 303.

## THE LEGAL STATUS OF THE UNITED MINE WORKERS OF AMERICA

When the United Mine Workers of America, some five or six years ago, were carrying on the campaign of disruption that ended in the disastrous strikes of 1909 at various Nova Scotian coal mines, the coal operators were greatly laughed at because they stated their belief that the activities of the U. M. W. A. were not entirely unconnected with the desires of the American coal operators to control the markets where Nova Scotian coal came into sharp competition with coal from the United States. Later developments proved that the suspicions of the Nova Scotian coal owners were very well founded, and an interesting sidelight on the local situation is given by an important judicial decision recently handed down in est Virginia in connection with an injunction against the U. M. W. A. asked for by the Hitchman Coal & Coke Co., of Wheeling, West Virginia.

In 1909, Judge Dayton, of the District Court for the Northern District of West Virginia, granted a preliminary injunction against the U. M. W. A. restraining them from picketing the mines of the Hitchman Coal Co. After legal proceedings extending over the whole of the intervening period, Judge Dayton, in December, 1912, confirmed the injunction and made it perpetual. The reasons actuating the decision are so apposite to the conditions that existed in Nova Scotia previous to the strikes of 1909 as to be well worth quoting. Judge Dayton sums up as follows:

"I conclude, therefore, that this organization, known as the United Mine Workers of America, is an unlawful one, because in its constitutions, obligations for memberships, and rules which (1) requires its members to surrender their individual freedom of action, (2) seeks to require, in practical effect, all mine workers to become members of it whether desirous of doing so or not, (3) seeks to control, and restrict, if not to destroy, the right of the mine owner to contract with its employees independent of the organization, (4) to exclude his right to employ non-union labour if he desires, (5) to limit his right to discharge, in the absence of contract, whom he pleases, when he pleases, and for any cause or reason which to him seems proper, (6) assumes the right on its part, by and through its officers, to control the mine owners business by shutting down his mine, calling out his men on indefinite strike in obedience to their obligation to the union, whether the men desire to quit work or not, whenever the union's officers deem it for the best interest of the union, regardless of the rights and interests of the mine owner, and regardless of his direct loss and damages and such indirect loss and damages as may be incurred by him by reason of the resulted violation of contracts by him with others.

"I further conclude that it is an unlawful organization because of its procedure and practices in that (1) it seeks to create a monopoly of mine labour such as to enable it, as an organization, to control the coal-mining business of the country, and (2) has by express contract joined in a combination and a conspiracy with a body of rival operators, resident in other states, to control, restrain, and to a certain extent destroy the coal trade of the State of West Virginia. It has spent fourteen years of time and hundreds of thousands of dollars to accomplish this unlawful purpose. The rules of law relating to the responsibility of individual members concerned in such a combination are plain and well defined."

The coal operators who are joined with the U. M. W. A. in this injunction are the unionized operators of Western Pennsylvania, Indiana, Ohio, and Illinois, known as the "contracting" States. The leaders of the U. M. W. A. have undertaken, at the request of the coal operators of these four States, to unionize West Virginia, hence the strikes at Cabin and Paint Creek that have been distinguished by the anarchy which seems to be inseparable from the methods of the U. M. W. A.

From a strategical point of view, it was no doubt very good business on the part of the U. M. W. A. leaders and the Pennsylvania operators to attempt to absorb and control the mine workers of Nova Scotia. Had these gentlemen succeeded it is beyond doubt that last year, instead of the Nova Scotian coal mines producing their record output, and thereby netting to the Provincial treasury the largest sum for royalties yet collected, they would have become caught in the maelstrom of American labour politics, and would have been laid idle by the leaders of the U. M. W. A. in "sympathy" with the strikers in Illinois and other places in the States. From their actions in the past it is evident that the thoughtful miners of Nova Scotia do not intend to sacrifice themselves to the inordinate ambition of the labour oligarchy in the United States, particularly when it is seen that the effects of the U. M. W. A. strikes smooth the path of the sales agent of the United States coal operator.

## THE EIGHT HOUR ACT

The Ontario Legislature has this month passed an Act that specifically limits the time per day that any workman can spend underground. The text of the Act will be found in another column. It is brief, concise, and comprehensive. Despite the warm protests of mine managers it was most expeditiously passed through the House.

The Hon. Mr. Hearst, Minister of Mines, is the putative father of the Act. It is fitting that this should be so. It is not fitting, however, for any Minister to tamper wih a principle in the manner that Mr. Hearst has. Clause 5 of the Act is specious, so specious as to rouse immediate criticism. By this clause the Lieutenant-Governor in Council is empowered, upon the recommendation of the Minister, to suspend the operation of the Act in so far as any iron mine is concerned. Except for the general provision that "in the event of great emergency or grave economic disturbance," no other class of mine is granted immunity.

Not for a moment would we impugn the Hon. Mr. Hearst's motives. Seeing, however, that he represents an iron-mining constituency, we feel it but fair to remark that had he known the needs and disabilities of other branches of mining in Ontario as well as he knows those of iron-mining, he would never have consented to the present form of the Act.

We have pointed out several times that the miner, of all industrial employees, is probably the best paid, the most comfortably housed, and the most fairly treated. It is, therefore, not seemly that the industry of mining should be experimented upon. There are grave abuses in many trades that cry for remedy. Why not have dealt with these first?

## THE CANADIAN MINING AND EXPLORATION COMPANY

The first annual report of the Canadian Mining and Exploration Company, Limited, covers the last eight months of the year 1912. During that period no less than 428 projects were submitted to the company, and considered by its officers. None was accepted. "Only a few," says Mr. Ambrose Monell, the president of the company, "proved sufficiently attractive to warrant "thorough examination and report. Some of these pro-"perties were promising mines and prospects, but the "terms under which there are at present available give "inadequate opportunities for profitable business."

Of the total, 285 projects were of Canadian origin, 110 came from the United States, 21 from Mexico, and the remainder from Central and South Americas, the Malay States, and South Africa.

Mr. Monell does not consider this discouraging. He alludes to the fact that very much valuable information has been gained, information that will be of inestimable value in the future.

Our readers will recall that the Canadian Mining and Exploration Company is an international organization with headquarters in New York and a central Canadian office in Toronto. The shareholders include many of the most prominent Canadian and United States financiers. The capitalization of the company is $5,000,000, of which $2,500,000 has been subscribed. This sum is so invested as to bring the company an annual income of about $125,000. Thus ample provision is made for the employment of a large staff of engineers.

Although many interests are represented in the company, the prime object of its existence is to develop Canadian mines. It is, therefore, a trifle surprising that not one of the many mines and prospects considered has been purchased. This cannot be due entirely to the character of the properties themselves. Nor can it be attributed justly to uniformly prohibitory prices asked by the owners. To a large extent, the refusal of 285 Canadian mining properties must be set down to a policy of extreme caution on the part of the company. No doubt during the future this praiseworthy deliberateness, we shall not call it timidty, will be modified.

# THE HOLLINGER REPORT

In the forefront of the revival of gold mining in Canada stands the Hollinger mine. The shares of Hollinger Gold Mines, Limited, are the thermometer of the mining share market. The mine itself is the centre of interest in Porcupine.

While this condition is essentially due to the character and extent of the Hollinger ore bodies, it has also been brought about by the sane attitude of the management. The public has been kept thoroughly in touch with development, and results have been regularly announced. In brief, the management has confidence in the mine, and the public has confidence in the management.

The second annual report of the company has just come to hand. It contains much interesting matter and thoroughly deserves comment. Part of the report is reprinted in this issue of the *Canadian Mining Journal.* Here we shall touch upon only the salient features.

Up to the end of 1912 the Hollinger mine paid three dividends, each of $90,000. The total profits were $600,664.42. Of this sum $101,801.69 was carried forward as a balance, $106,223.54 was written off the plant, and $102,639.19 was written off development. The average value of all the ore treated was $21.44. The tonnage put through the mill amounted to 45,195 tons, having a gross value of $970,304.89. The total recovery was $933,681.53. Mining costs were high, $3.588 per ton. Milling costs averaged $1.693 per ton of ore treated. The total cost per ton was $6.744, of which $0.508 per ton was charged to expenditure incidental to the strike. Both milling and mining costs were abnormal, and both will be lower during the present year.

The ore reserves are estimated at $644,540 tons containing gold valued at $11,271,400, an average of about $17 per ton. This compares favourably with the estimate of one year ago when the value of reserves was placed at $10,230,000.

Our readers will draw their own conclusions from the Robbins report as reprinted in this issue. No doubt it will strike most of them that it is merely a matter of time when the tenor of Hollinger ore will necessarily be somewhat reduced, and, as a natural consequence, the plant will be enlarged. But be this as it may, the fact obtrudes itself that the Hollinger mine is in a strong and healthy condition.

# EDITORIAL NOTES

At the recent annual meeting of the Canadian Mining Institute, Mr. Henry Bertling, of Toronto, gave a demonstration of the Pulmoter, a device for producing artificial respiration by delivering oxygen automatically to persons rendered unconscious by gas poisoning, drowning, or electric shock. The value of this apparatus in connection with mine rescue work is unquestionable, and in recognition of its utility in this respect the device was recently awarded, by the Jury of Awards of the American Museum of Safety, the Scientific American Gold Medal, which is presented annually "for some three years, and exhibited in the Museum's collections."

From an authoritative source, we are given to understand that while the London money market is for the time being disinclined to consider proposals for the financing of Canadian industrial undertakings, however sound, there is a revival of interest in Canadian mining for which it is not difficult to secure capital. This is no doubt due to the successful results attending the operation of one or two mines in the Cobalt district and elsewhere in which British capital is invested, and also to the rehabilitation of the mining industry of Canada in general. Unfortunately advantage has already been taken of this favourable disposition by a class of mine-peddlers and promoters whose activities in the past are largely to blame for the non-success of the majority of the British-owned mining enterprises in the Dominion, and a number of very dubious "propositions" are now being offered in London. If the British capitalist would take the very obvious precaution of securing the advice of responsible engineers resident in this country before taking any final steps, the percentage of failures to successes would be very considerably reduced.

The proposal for a union of the Mining and Metallurgical Society of America and the American Institute of Mining Engineers, has been already endorsed by the Council of the former organization, and the question will be determined finally this month by letter ballot of the members. In effect, the plan as outlined is the same as that projected some few years ago in Canada, when it was suggested that there should be an association of mining engineers, distinct from the Canadian Mining Institute, but affiliated with it and requiring that membership in the Institute should constitute an essential qualification for registration in the former. In some respects it is unfortunate that this project was allowed to drop. In the United States the Mining and Metallurgical Society has served a useful purpose, which as a "section" of the American Institute it will be able to continue without restriction. The same opportunity presents itself in Canada.

In a recent bulletin issued by the United States Bureau of Mines, some astonishing figures were presented showing the enormous waste in connection with the production of coal in that country. Thus it is stated that in 1912, in producing 500,000,000 tons of coal there was wasted or left underground in such condition that it probably will not be recovered in the future 250,000,000 tons; while there was turned into the atmosphere a quantity of natural gas larger than the total output of artificial gas during the same period in all the towns and cities of the United States. If this was the case in the United States, it is safe to assume that conditions in Canada would prove to be worse. In the Province of by men without capital to develop their properties pro- Alberta especially, where many small mines are "worked" perly, and who are only concerned in making a few dollars quickly without regard for the future, the waste is appalling; and it is high time for legislative interference to prevent it.

---

Legislation in a right direction has been enacted recently in Montana for the regulation of the sale of mining securities in that State. Under the new law every company offering stock or securities for sale is obliged to file with the authorities an itemized statement showing the actual financial condition, the nature and extent of its properties, copies of all contracts, literature and advertising matter, and other particularized information. The State appoints a commissioner who is given authority to investigate the affairs of any company, and no dividends may be paid without his approval. With these restrictions "wild-catting" in Montana, provided, of course, the law is effectively administered, should not prove a too easy undertaking.

---

Two of the bright spots in the mining firmament of Eastern Ontario are the Cordova gold mine and the Belmont iron mine. At the former about 100 tons of gold ore are being treated per day. At the latter, preparations are practically completed for the shipment of substantial quantities of iron ore. At both mines exceedingly cheap power is being used, and both seem to have overcome the disabilities under which they formerly laboured.

---

## PERSONAL AND GENERAL

Mr. L. K. Armstrong, of Spokane, Washington, editor of the Northwest Mining News and secretary of the Spokane Local Section of the American Mining Institute, has been in correspondence with the secretary of the Western Branch of the Canadian Mining Institute, relative to the joint meeting of the two organizations it is intended to hold at Rossland, B.C., on May 22 and 23.

Mr. W. M. Brewer has returned to Victoria, B.C., after an absence of eight months, spent in Alaska, where, in the vicinity of Valdez, he has been prospecting a gold mining property and installing a small stamp mill.

Dr. A. E. Barlow will probably again visit Western Canada during the ensuing summer.

Mr. D. C. Botting, of Seattle, Washington, State Inspector of Coal Mines, though unable himself to attend the meeting of the Western Branch of the Canadian Mining Institute, held at Nanaimo last month, was instrumental in inducing Mr. J. F. Menzies, of Rosyln, Wash., to go in his stead and read a paper there.

Mr. Wm. Blakemore, of Victoria, B.C., editor of "The Week," now includes in that weekly publication a mining column, which is edited by himself.

Mr. L. A. Campbell, of Rossland, B.C., general manager of the West Kootenay Power and Light Co., who represents the Rossland constituency in the British Columbia Legislative Assembly and is chairman of the Mining Committee of that body, was last month entertained at a complimentary smoker at Rossland on his return to that city after the close of the recent session.

Mr. F. Napier Denison, of the Dominion Meteorological Office, Victoria, B.C., has accepted an invitation extended to him by Prof. Andrew C. Lawson, professor of geology and mineralogy at the University of California, to deliver two addresses—one technical and the other popular—before the annual meeting of the constituted societies of the Pacific Association of Scientific Societies, in connection with the special research seismological work he has for some time been engaged in. Mr. Denison, who went West from Toronto, has on three occasions addressed meetings of the Western Branch of the Canadian Mining Institute on the subject of "Earthquakes, Strains and Stresses, in Relation to Coal Mine Disasters."

Mr. W. E. Finch, of Spokane, Washington, manager for a syndicate that is developing several mines in Slocan district, British Columbia, under option of purchase, lately spent several days in Victoria.

Mr. Francis Glover, formerly employed at the Extension colliery of the Canadian Collieries (Dunsmuir), Limited, Vancouver Island, B.C., has been appointed superintendent for the Princeton Coal and Land Co., operating a coal mine at Princeton, Similkameen, in succession to Mr. James Holden, resigned.

Prof. J. C. Gwillim, of the School of Mining, Kingston, expects to spend next summer in Alberta, on some of the coal lands of the Canadian Pacific Railway Department of Natural Resources.

Mr. W. S. Haskins, who some years ago was connected with mines in Rossland, B.C., has latterly been engaged in developing mineral calims in the Hazelton part of Skeena River district, British Columbia.

Prof. Arthur Lakes, of Denver, Colorado, a well-known contributor to various mining journals, is now resident in the vicinity of Ymir, Briitish Columba, with his son, who is manager of the Wilcox gold mine in Ymir camp.

Major Ainsley Megraw, of Hedley, Similkameen, B.C. (an old Ontario man), editor of the Hedley Gazette, has done good service to the mining industry of Hedley camp by exposing the discreditable career of one C. H. Brooks, who had commenced a campaign of unscrupulous advertising in the City of Vancouver with the manifest intention of obtaining money from the public, professedly for the development of a mining property near Hedley. Mr. Brooks has since left British Columbia.

Sir Richard McBride, Premier and Minister of Mines of British Columbia, on the occasion of his responding to an invitation to deliver a Charter Day address at the University of California, received the honourary degree of Doctor of Laws.

Mr. F. M. Sylvester, of Spokane, Washington, assistant to the general manager of the Granby Consolidated M. S. and P. Co., lately spent a week or two in the British Columbia coast cities of Victoria and Vancouver.

# TENTH INTERNATIONAL GEOLOGICAL CONGRESS MEXICO, 1906.*

By WILLET G. MILLER.

The Tenth International Geological Congress is not wholly unknown even to people in this country who take little or no interest in geology or mining.

The audience may recall the attention which the Canadian newspapers gave to certain features of the Mexican Congress. One morning, for instance, it was announced with startling headlines that a distinguished congressionist from Montreal had been overwhelmed by a volcanic outburst on Mount Colima. Another day telegraphic despatches told in no less terror-inspiring language of a snowslide on Mount Orizaba that carried with it a Toronto congressionist three thousand feet to the depths below. Happily these despatches, copies of which with brief, but appreciative obituary notices I found in my scrapbook the other day, proved to be but fabrications of press agents, and all the members of the Canadian contingent returned to their native land, a little the worse for wear, perhaps, but still in a satisfactory state of convalescence.

In describing the Mexican Congress it will be well to note briefly various features of the work of organization, the excursions, the sessions, entertainments and finally the achievements or beneficial and lasting results of the congress. A knowledge of these features should be of value in making arrangements for the Canadian Congress, and in carrying out the work. Incidentally I shall refer to the natural attractions that Mexico had in 1906 for entertaining a large body of people. If it is decided that our country, compared with Mexico, is lacking in natural attractions or in facilities for entertaining, then we should attempt to make up for these in other ways. Personally I believe that Canada, while offering a great contrast to Mexico, will prove no less attractive to our visitors, and that the achievement of the Twelfth Congress will be of much importance to science and to their country.

The following passage from Prescott, describing the march of Cortez' conquering army nearly 400 years ago, from the sea to the valley of Mexico, shows the character of the scenery:

"Nothing could be more grand than the view which met the eye from the area on the truncated summit of the pyramid. Toward the north stretched that bold barrier of porphyritic rock which nature has reared round the Valley of Mexico with the huge Popocatepetl and Iztaccihuatl standing like two colossal sentinels to guard the entrance to the enchanted region. Far away to the south was seen the conical head of Orizaba soaring high into the clouds, and nearer the barren, though beautifully shaped Sierra de Malinche, throwing its broad shadows over the plains of Tlascala. Three of these are volcanoes, higher than the highest mountain peak in Europe, and shrouded in snows that never melt under the fierce sun of the tropics. At the foot of the spectator lay the sacred city of Cholula, with its bright towers and pinnacles sparkling in the sun, reposing amidst gardens and verdant groves, which then thickly studded the cultivated environs of the capital. Such was the magnificent prospect which met the gaze of the conquerors, and may still, with slight change, meet that of the modern traveller as from the platform of the great pyramid his eye wanders over the fairest portion of the beautiful plateau of Puebla."

For some years many geologists had expressed the hope that a meeting of the Congress would be held in Mexico at a time convenient for the government of the country and the Mexican geologists. The publications of the Geological Institute of Mexico had shown that the country offered a vast field for geological studies of all kinds. Moreover, being such a beautiful land and so interesting from other points of view, its natural features having been so well described by Humbolt and its early history in the fascinating pages of Prescott, and possessing great mineral wealth and historic mines, offers unexcelled attractions to visitors, especially to those from more northern regions.

At the Ninth Congress, held in Vienna in 1903, the hope of having a meeting in Mexico was realized, it being decided to hold the tenth meeting in that delightful country. Canada had also sent an invitation to Vienna, but the attractions of Mexico and the hearty invitation extended by the Government and the Geological Institute won the day for the southern country.

The invitation having been definitely accepted, a Committee of Organization was formed. This committee solicited the co-operation of all geologists residing in Mexico, and of a certain number of mining and other industrial companies and finally that of the governors and high officials of various states of the Republic whose assistance would be valuable in the conduct of the excursions.

The Executive Committee was composed for the most part of members of the National Geological Institute (or Geological Survey), the president being the director of the Institute. The committee was charged with all the preparations for the Congress, both of a scientific and of a purely administrative character.

The organization committee had over ninety members among whom were the foreign directors of several companies, e.g., Sir Weetman D. Pearson and Mr. John Hayes Hammond. The executive committee consisted of twelve members.

Local committees were organized in various states of the Republic to assist with the work of the Congress and to arrange for receptions and other entertainments. In most cases, during the excursions the Governors of the states acted as chief hosts.

### Financial Assistance.

In addition to other assistance, the Mexican Government made a grant of \$164,000, or \$82,000 in gold, for the expenses of organization, the arranging of excursions, the publishing of the guide book and for other purposes.

All the railways in Mexico gave important reductions, at least fifty per cent., in the price of transportation. Half fare rates from all points east of Buffalo, Pittsburg and Atlanta to Mexico and return were

*An abstract of this paper was read at the meeting of the Organization Committee of the 12th Congress in Ottawa in March. About six-sevenths of the time devoted to the 12th Congress will be occupied with excursions, which will be of as much interest and value to mining engineers or to geologists, hence the Congress might properly be called a "Mining and Geological Congress."

given by the United States railways. The railways controlled by the Pearsons and by the Copper Queen and other companies, not only gave free transportation but they made the excursionists their guests in all respects.

The Copper Queen Company, and other companies, whose hospitality the writer had the good fortune to receive, sent a splendidly equipped train to El Paso to meet the excursionists at the border. For six days the excursionists were the guests of these companies, visiting the smelters at Douglas and the mines of Bisbee, Cananea and Nacozari.

### Steamboat Fares.

European members were encouraged to visit Mexico by the government paying for a reduction of one-half of the steamboat fares on specified lines, viz., Hamburg-American and Ward, either to Vera Cruz or to New York.

The "Compana Translantica Espanola" gave a reduction of thirty-three per cent., and the Mexican Government made the reduction up to fifty per cent. by paying the difference.

The Mexican Government also assisted transportation during the excursions by furnishing saddle horses from detachments of the rural police. Horses were always available when needed. (I am sure it would be most interesting to this audience were one of the Canadian excursionists to relate his experience in riding one of these metalled rurale chargers from the railway station at San Juan to the Pyramids of the Sun and Moon, through roadways lined with stone walls and giant cacti, across the parched Aztec plain even to the slopes of the pyramids themselves. Compared with his ride, that of John Gilpin was merely a canter in a village street, and Mazeppa's steed, so well described by Byron, was not more wild and free. In his account of the excursion, however, President Aguilera speaks of it as forming a "joyous caravan," some on foot, others in carriages, but the greater number "à cheval.")

### Excursions.

Preceding and following the sessions which were held in the City of Mexico from Sept. 6th to the 14th, several excursions were given under the patronage of the government. The earlier excursions consisted of one to the south lasting nine days, one to the east, three days, one to Jourallo, thirteen days, and one to San Andres and Colima, twelve days.

After the sessions there was an excursion limited to 250 persons to the north, through the great mining regions, that lasted twenty days. The excursionists occupied two trains, each person being given a section to himself. Connected with this excursion was the complimentary one to mining and smelting centres given by the Copper Queen and other companies in Arizona and Sonora.

After the excursion to the north there was another, essentially for paleontologists, beginning October 6th and lasting eight days, to the southern part of the Republic.

During the sessions four extremely interesting excursions lasting not longer than a day each were given. They were held on alternate days so as not to interfere with the sessions.

One of them was to Coyoacan to see the great lava flows, which, while recent in a geological sense, are prehistoric. Human remains, fragments of pottery, cobs of Indian corn and other materials show that the flow took place after the area was occupied by man.

The second excursion, to the historic City of Cueruavaca, was organized by the Geological Society of Mexico, and the excursionists were welcomed by the Governor of the State of Morelos and a reception committee. The park, the botanic garden, and especially the palace of Cortez, which still stands little impaired by time, are all of historic interest. At the banquet, given on this as on all other excursions, one of our Mexican hosts cheered us with the words: "Ladies and gentlemen, I drink to the glory of your countries; friends of Mexico I drink to your health."

The Minister of Public Instruction "desiring to show his profound regard for the congressionists" organized the third excursion, to visit the Pyramids of the Sun and Moon. The excursion was under the direction of the Inspector of Archeological Monuments. The pyramids proved to be most interesting, resembling those of Egypt, and the banquet of the afternoon in the grotto or huge cave was in all respects unique. It is much larger than the historic one described by Virgil, in which Dido and Aeneas sought refuge from the elements. In fact the Porfirio Diaz cave is large enough to have accommodated the entire retinue of these famed personages, so that one pair need not have been left in lonely isolation.

In his memoirs, my friend Aguilera has not tarried long in describing this cave banquet, but we recall that the Director of Public Works received us with the words, "Mexico welcomes all who have good will in their hearts and science in their brains."

The fourth of these excursions was made to the famous silver mines of Pachuca where a welcome was extended and a banquet provided by the Governor and other high officials of the State of Hidalgo and of the City of Pachuca.

### Sessions.

The opening session was held at 11 o'clock on the morning of September 6th, in the great reception hall of the National School of Engineers, under the presidency of his Excellency, the President of the Republic, General of Division Don Porfirio Diaz, high protector of the Congress. There were also present the Diplomatic Corps and the Ministers of State.

I shall not say much concerning the sessions, except that like the excursions, receptions and entertainments they were a credit to the Mexican geologists, who had devoted much care and attention to securing papers on important subjects and arranging for discussions on leading themes. Most of us do not attend geological congresses in order merely to listen to the reading of papers and to discussions. While at such a gathering these are valuable and necessary, persons visiting a country as attractive as Mexico desire to learn something of its geology at first hand, and to become acquainted with fellow students of geology from other parts of the world.

Four major subjects were selected by the executive committee for discussion, and the promises of several men to lead in each subject were secured some months before the sessions began. The subjects were: Conditions of Climate in Geological Epochs, Relations Between Tectonics and Igneous Masses, Genesis of Metalliferous Deposits, and Classification and Nomenclature of Rocks. Papers were read and discussions took place on various other subjects during the session.

### Receptions and Entertainments.

While these have been referred to incidentally in preceding notes it will be well to mention them more systematically in order to show what may be expected of us in Canada during the coming summer. In many ways Mexico possesses, or did possess in 1906, facilities for entertaining a larger body of people than can be equalled in but few countries. We in Canada cannot hope, I fear, to make the social side of the Twelfth Congress so enjoyable and attractive as was that of the Tenth. However, Canada's newness, a country in the making, will appeal to many.

On the evening of the 5th of September, preceding the opening session, there was a reunion of the congressionists at the restaurant in the historic wood of Chaupultepec. As Aquilera says, "the time was spent in a manner very animated," and there was a dinner with music by the artillery band.

On the evening of the following day, the members of the Geological Institute held a reception. The interior of the hall was decorated with the flags of all the nations represented at the Congress. There was band music and a "champagne supper." Three hundred persons were in attendance.

The morning of the 7th was spent in visiting public institutions of the city, carriages being furnished. Visits were made to the National Museum, the National Medical Institute, National Library, the Cathedral, and the Academy of Fine Arts. Small parties visited the National Astronomical Observatory.

In the evening of this day the Government Council of the Federal District, and the Municipal Council tendered a banquet at the Municipal Palace. Flags of various nations were again in evidence here. Those in attendance at his banquet included representatives of the Diplomatic Corps and members of the Mexican Government. At the head table presided the Vice-President of the Republic. The souvenir of the banquet took the form of a beautifully illustrated volume descriptive of the city.

A concert, with "champagne lunch" was given on the evening of Sept. 8th. On the evening of the 10th a reception was held by one of the members of the government.

President and Madame Diaz on the evening of the 12th, offered a "tea" in the beautiful chateau de Chaupultepec. The cards of invitation announced a "five o'clock tea," but in reality the presidential residence had been prepared for a soiree concert. Arriving at the chateau at five o'clock the congressionists were received by President and Madame Diaz. At this reception were the members of the Diplomatic Corps and high officials of the government.

From the high balcony of the chateau a magnificent view could be had of the distant volcanoes, Popocatepetl and Ixtaccihuatl.

At six o'clock commenced a concert in which the principal Mexican artists took part. At seven dinner was served, and at 11.30 the guests departed having been delightfully entertained for over six hours.

On the evening of the 14th a "banquet fraternal" was held.

The entertainments provided at various places during the excursion were numerous and showed the interest that the Mexican people as a whole took in the congress.

### Achievements of the Congress.

Of great importance and variety were the achievements of the Mexican Congress.

For instance, in referring to the Geological Guide Book, prepared under the direction of the Executive Committee, a United States technical journal, Economic Geology, said:

"Mexico has during the last decade become the seat of such expensive mining operations that even the most meagre geological information is eagerly welcomed by all geologists and mining engineers, and a publication so thoroughly and carefully prepared as this geological guide must be at once recognized as having an unusual scientific and practical value. Beautifully illustrated, it gives sections and maps of all important mining districts and noteworthy geological features of the various regions covered by the excursions of the Congress. Certain of the papers on economic geology furnish the only available information on more than one district of widely recognized commercial importance.

"Mexico is to be congratulated on having placed in the hands of professional men information so long desired on mining districts whose remote and unknown geological character has in no small measure handicapped successful mining in the regions concerned."

Of the geological map of North America, prepared in co-operation by the United States, Mexico and Canada, the same journal said:

"The second publication which accompanied the guide is scarcely of less importance and value to students of geology. Nothing so comprehensive has every appeared in the way of geological maps."

(While our guide books and maps cannot be said to deal with areas wholly undescribed, still they put the descriptions in handy form, and give a good synopsis of the literature. Will not our publications be as valuable to Canada as were those of the Tenth Congress to Mexico in making known the country's mineral resources and geology?)

The excursions were not less valuable than the publications. They gave members of the Congress exceptional opportunities for becoming acquainted with many of the large and historic mines, the geology, archaeology and numerous other features of great interest in the Republic. (Certain of the congressionists, at least, have shown their interest in the natural resources by making investments in the country and have induced others to do so.)

The published discussions on various geological themes during the sessions have a lasting value.

Not the least of the important results of the Congress was the kindly feeling engendered in the hearts of the visitors towards Mexico and her hospitable people. During the last month it was with feelings of sadness that we read of the partial destructions of that city which Diaz attempted to make, and in many respects succeeded in making, the most beautiful in North America.

We must all admire the achievements of President Diaz, one of the greatest military statesmen of his own or of any age. Weighted with years he had at last to retire. May another leader arise to bring peace and continued prosperity to the great, the beautiful, and the historic country!

# THE OCCURRENCE OF PYRITES IN CANADA

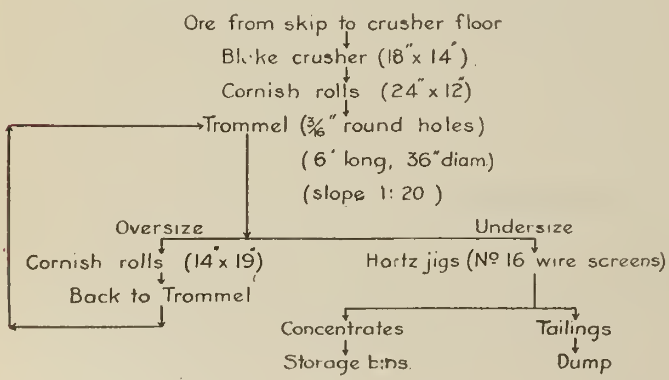
Notes from the Report* of Dr. Alfred W. G. Wilson.

(Continued from last issue.)

### Hastings District.

Bannockburn Pyrite Mine.—Lot 25, Concession VI., Madoc Township, Hastings County, about a mile southeast of the Village of Bannockburn. 1898, openings were made for iron ore, and Stephen Wellington, of Madoc, shipped eleven carloads of bog iron ore or limonite to the Hamilton Iron and Steel Company. This ore, which ran upwards of 38 per cent. metallic iron and low in sulphur, was merely the gossan capping of iron pyrites deposits. These were further prospected by Thomas Burnside and William Coe of Cleveland. In the summer of 1900, they transferred their lease to the American Madoc Mining Company, who abandoned operations at the McIlwraith in favour of the more accessible deposit. The gossan capping at the Bannockburn mine varied in depth from 8 to 15 feet. A pit about 80 feet in diameter and 90 feet deep was sunk, but at this stage had to be abandoned. Through the oxidation of low grade ore, large masses began to scale off the sides of the pit, necessitating either an expensive system of square set timbering or cessation of the work. In the meantime a new lens had been opened up about 500 feet south of the open pit. A shaft was sunk here, levels run every 60 feet, overhaul stoping adopted, and a skipway with guard rail provided. A battery of boilers and a five-drill, straight-line air compressor were installed, which supplied the drills, steam being used for the pumps. In later years this method of working was abandoned for the following practice. A pit or trench 8 or 10 feet in depth was sunk and this

FLOW SHEET, MILL OF COLE MINE, ST. LAWRENCE CO., N.Y.



was followed by underhand stoping back the full length of the lens. For convenience in mucking, the skip was replaced by a bucket; the lens pitched to the north and was penetrated by the shaft so that the operation of the skip had become impossible. The skids at the top of the rock house were inclined to the horizontal. As the loaded bucket was hoisted into this position, a chain was hooked into a ring in its bottom, the skids were pulled apart, and the bucket was dumped by lowering it slightly. The bucket was then hoisted, the chain unhooked, and it was then thrown back on the skids and lowered. The bucket loads were dumped on steel bars, placed 6 inches apart above a series of grizzlies spaced to one-half inch. The fines from the grizzlies discharged through the rock house floor and the culled lump ore was wheeled out to a loading dock, whence wagons drew it half a mile to the siding of the Central Ontario Railway.

Some shipments from the open pit graded from 46 to 48 per cent. of sulphur, and some from the south lens did not run higher than 37 per cent. A fair average of the property would be 40 per cent. of sulphur. The ore is hard and makes very little fines.

The country rock is a chlorite schist, showing talcose or micaceous alteration in the vicinity of the ore bodies. The south lens and enclosing schist strike slightly west of north until west of the open pit, when a fold of 90 degrees angle turns the strike to a little north of east. The south lens dips with the country rock to the east, and the open pit in a similar manner dips to the south. Unfortunately the surface of the schist at the apex of the fold was covered by a deposit of limestone, which was subsequently metamorphosed to a calc schist, but there is no evidence whatsoever of faulting. Folding, whether of a simple nature or a pitched anticlinal subsequently eroded, produced the lines of weakness through which the pyrite-bearing solutions seeped, the deposits being formed by replacement. The ore separates readily from the fairly good foot wall, but towards the hanging, the grade lowers, and it shades gradually into the schist. It is impossible to obtain fresh specimens of the schist. Originally it was probably horn-blendic; at present it is chloritic, due probably to surface weathering and the influence of the mineral bearing solutions from the adjacent vein. The south lens is 160 feet in length, and varies from 8 feet to 15 feet in width. The mine employed from 35 to 40 men and shipped during its six years of operation about 580 tons per month. All the ore went to the works of the General Chemical Company at Buffalo.

Although the ore fell off neither in grade nor quantity with depth, yet on account of the open pit method of mining (the south lens being stoped out to a depth of 275 feet), and the tendency of the walls to scale, mining became so hazardous that the operations were abandoned in August, 1906.

The Hungerford Fahlband.—The Hungerford fahlband lies about 5 miles east of the Village of Tweed north of the Canadian Pacific Railway. It strikes north 65 degrees east, and is easily traceable for two miles. Level farm land to the south is underlain by garnetiferous crystalline schist cut by massive diorite. About 500 yards north of the deposits, the schists have been invaded by a pink hornblende granite that now rises above the surrounding country, forming a series of rugged hills (locally called the Bald Mountains); this granite has protected the ore bodies from erosion. The deposits are strung along the contact of the diorite and the schist, the strike of the lenses, the contact, the fahlband, and the schists being identical.

Hungerford Mine.—Lot 23, Concession XII., Hungerford Township, Hastings County. This mine was opened 30 years ago, by the American Madoc Mining Company, as a gold property, and a smelter was erected to extract gold from the barren pyrite. The present operators, the Nichols Chemical Company, re-opened the mine in June, 1903. Owing to some difficulty about the title, the mine was closed down in August, 1904, but operations were resumed in August, 1905, and have since been continuous.

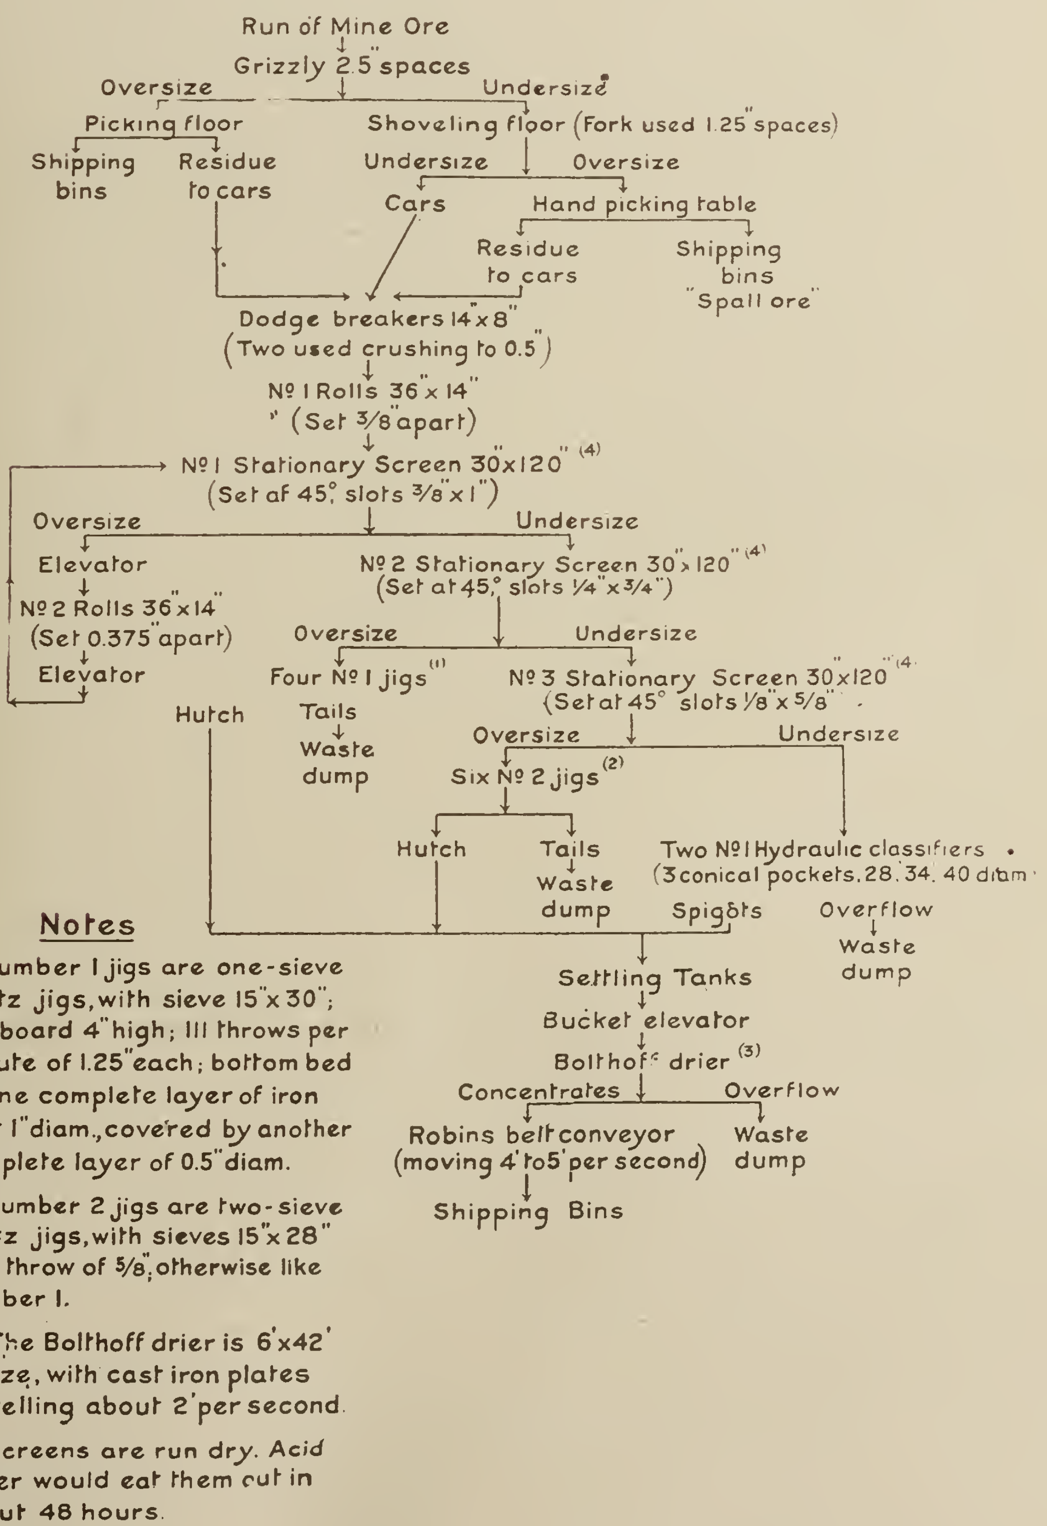
*Dressing and Uses.—By Dr. A. W. G. Wilson, Mines Branch, Ottawa.

The first shaft was sunk in the diorite footwall to a depth of 300 feet, and levels were run every 100 feet. Two other ore bodies were discovered, one from surface outcrops, the other during the progress of underground work. On each level cross cuts were made to catch these ore bodies, known respectively as the middle and north lodes. There are now two shafts on the property, and about 3,500 feet of drifting has been done on the ore bodies on five levels, exclusive of cross cuts, and the sixth level is now being opened up.

In exploitation work winzes are usually carried down in advance of shaft sinking. At present the main shaft is being sunk from the 5th to the 6th level.

The middle lode has no visible outcrop on the surface. It lies 85 feet to the north of the south lode, and was found when drifting towards the north lode on the first level. Cross cuts have also been run through this lode on the 2nd and 3rd levels, and considerable exploratory work has been done upon it. It carries ore on the 1st and 3rd levels, but not on the 2nd. This lode, on

FLOW SHEET, SULPHUR MINES AND RAILROAD COMPANY,
SULPHUR MINES, VIRGINIA.



the first level, has a width of about 6 feet of high-grade ore, but on the 2nd level it contains a very large quantity of calcite.

The north lode lies 45 feet farther north. When first cut, it was 22 feet wide, 17 feet being through massive pyrite. The length of this lode, as indicated on the surface, is over 500 feet. On the 3rd level, drifts have been run along the lode 370 feet east and 250 feet west of the cross cut that runs to the south lode. The width varies between 6 and 22 feet.

The mine is fairly dry, very little water being encountered, and that chiefly on the north lode.

Much of the ore that has been hoisted has been secured during development work. Some stoping has also been done on the three upper levels. At present the bulk of the ore hoisted is obtained during the development work.

The ore is coarsely granular and makes a large percentage of fines. The main impurity of calcite, though there is also some quartz present. A small quantity of pyrrhotite occasionally occurs, mainly in the north lode next the footwall.

. . . . . . . .

At the present time only fines burners are used at the works. Hence no lump ore is required. In preparing the ore for the Herreshoff burners, the lump and spalls are passed through a No. 3 McCully crusher (capacity about 150 tons per day) and a set of Buchanan rolls, 24 inches by 14 inches. The lump and spalls are dry enough to be used at once. The fines from the mine are dried in a wood fired rotary dryer before being fed to the furnaces.

In shaft sinking, two machines are used, in drifting only one—both Ingersoll and Holman drills are in use. For stoping both Rand and Hartzog hammer drills are employed.

Overhand stoping is employed throughout the mine. The main drifts are run the length of the ore body. Chutes are placed about 20 feet apart, and an 8-foot ore pillar is left above the drift. The stopes are raised to within 8 feet of the level above, just enough ore being drawn off during stoping to give working room above the broken ore in the stope.

The drifts are 5 feet wide and 6 feet 6 inches high. Both the ore and rock break hard, and usually 19 or 20 holes are required to square a cut. Most of the drifting is done on contact.

Power is obtained from the Seymour Power and Electric Company, the generating station being at Campbellford, 40 miles away. The current is received at a voltage of 44,000, and is stepped down to 240 volts for use in the plant and mine.

All the ore mined is used directly in the acid works which has been erected on the property at Sulphide station by the Nichols Chemical Company. The average percentage of run of mine ore will be about 35 per cent., the fines being much higher.

The Canadian Pacific Railway main line between Montreal and Toronto crosses the southern end of the property, a little more than a quarter of a mile from the mine.

Ontario Sulphur Mines, Limited.||—The property of this company comprises the northwest quarter and the east half of lot 21, concession XI, township of Hungerford, Hastings county, having a superficial area of 150 acres. Work on the property commenced in March, 1908, and has been carried on continuously, save for a shut-down of two months in the summer of 1910. The pyrites deposit on which work has been done is located about half a mile east of the Hungerford mine. It appears to be a lens pitching towards the southeast.

The main shaft (14 by 7 feet) has been sunk to the 100-foot level. Below this it was narrowed to 10 by 7 feet and was carried down to 250 feet below the collar. On the 100-foot level drifts have been carried 84 feet west and 98 feet east along the lode. On the 200-foot level the west drift runs 17 feet and the east drift has been carried 170 feet from the shaft.** A cross cut has been run for 30 feet from the east drift on the 100-foot level; for 12 feet from the west drift on the 200-foot level; and for 27 feet from the east drift on the 200-foot level.

The work which is being carried an at present is largely for exploration and development.

The present plant consists of two upright boilers with a capacity of about 65 horsepower. The mine is provided with one 3-drill Clayton air compressor operating two Corkill and three hammer drills. The hoist is capable of hoisting 1,200 pounds 300 feet. The pumping equipment consists of a duplex steam pump for the boilers and one Cameron sinking pump.

It is proposed to install electric power by extending the power line of the Seymour Power Company from the plant of the Nichols Chemical Company less than three-quarters of a mile to the east. The shaft is to be straightened and a skip track installed. The new equipment will include a 2-ton electric hoist, and a 12-drill air compressor. A shaft house will be erected with ore sorting floor and bins. An aerial tramway will be run to the Canadian Pacific Railway where it crosses the company's lot about 1,800 feet from the mine and unloading bins will be provided at the siding.

The company are also considering the erection of a concentrating plant, but this will not be erected this year.††

The total shipments from the property up to the first of May, 1911, have been 4,821 long tons of ore averaging 36½ per cent. sulphur.

The Queensboro Fahlband.—This fahlband, which is near the eastern boundary of Madoc Township, strikes in a general north-of-east direction, and can be readily followed for a distance of two miles, stained, rusty and decomposed schists being discernible throughout that distance.

Queensboro Mine.—Lot 11, concession XI., Madoc Township, Hastings County. This property is located about one mile southwest of the Village of Queensboro, and one-half mile west of the Bay of Quinte Railway.

The deposit lies in a depression at the contact of a garnetiferous crystalline schist to the south, resembling that at Hungerford, and an intrusion of light grey granite to the north.

A small spring creek ran through the depression over a part of the deposit. This it was necessary to divert, and a shaft was sunk at the edge of the old creek bed, to a depth of 85 feet. At 50 feet in depth water came in to such an extent that a drift was driven to the east for 30 feet and a cistern was constructed into which the water was trapped by means of wall plates and troughs. At the bottom of the shaft, a drift has been run to the west for 25 feet, and a cross cut made 20 feet to the north. A drift was also driven to the west on the 50-foot level.

One hundred and fifty feet to the west another shaft has been sunk to a depth of 30 feet.

||Managing Director, B. A. C. Craig, National Club, Toronto; Mine Office, Tweed, Ont.
**In July, 1911.
††1911. The mine was closed near the end of this year.

About 100 feet southwest of the main shaft, a zone of highly pyritous rock was worked. Through this ran several lenses, up to 4 to 5 feet in thickness, of medium grade pyrite, shading off into leaner ore. One lens contains disseminated copper pyrites, which was worked by an open pit.

The mine was operated by the British American Development Company of Toronto.

The pyrite was hauled by teams to Queensboro Station and there shipped to the Contact Process Company at Buffalo. The first 21 cars shipped average 47 per cent. sulphur, and shipments up to the fall of 1906 amounted to 65 carloads.

The highest grade ore comes from a series of lenses close to the granite contact. That on which the main shaft is sunk has, at the shaft, a width of 15 feet and a length of about 50 feet, thinning out towards the ends. To the west is a similar lens, which shows a width, in a surface trench, of 20 feet of very high grade pyrite. The iron pyrites in these lenses is a hard, heavy, dense ore resembling a massive magnetite, the only impurity being thin veinlets of quartz. To the south is an extensive area of more or less imperfect impregnation, showing places from which a 35 per cent. sulphur ore can be quarried.

A noteworthy feature of this deposit is a small vein to the west of the workings which has a northwest strike and is about 2 feet wide. It has been opened by a trench 16 feet long and 4 feet deep. It cuts the formation at an angle of 45 degrees, and appears to possess well defined walls. The vein is composed of quartz, pyrite, copper pyrite and argentiferous jamesonite. This vein is of later age than the pyrite deposit. The jamesonite fills the interstices and is formed around crystals of pyrite. This vein possesses an interest on account of the rare occurrence of jamesonite in this country, and the present high price of antimony.

Canadian Sulphur Ore Company's Property.‡‡—N. ½ Lot 9, Concession X., Madoc. When this property was investigated by Mr. Fraleck in 1906, a series of pits and trenches had disclosed a belt of gossan over 500 feet in length, about 200 feet in width, and about 12 feet in depth. The gossan was mainly conglomerate with iron oxide as a cementing material; certain portions were a fairly good limonite. Here and there throughout the gossan, were found pyrite boulders up to 12 feet in diameter, but the ore body had not been located.

Subsequent prospecting and development has disclosed pyrite ore in a series of lenses in a fahlband, occurring in rocks of pre-Cambrian age. The lenses vary in width up to 20 feet. The ore is high grade, very little cobbing, if any, having to be done, and cars have been shipped running 40 to 48 per cent. sulphur. The ore is free from arsenic, zinc, lead, copper and calcium. It burns very satisfactorily, and is in good demand by sulphuric acid makers. The output goes mainly to Sulphide, Ontario, and to Buffalo, N.Y.

The main shaft is now down 135 feet, and a second shaft 400 feet west is down 50 feet. The property is equipped with an 80 h.p. steam boiler, 3-drill air compressor, steam hoist, air drills, pumps, and other necessary machinery. There is a comfortable boarding house for the men, and an office building. The property is still in the early stages of development, but the company expect to ship, shortly, at the rate of 30 tons a day.

The operating company is the Canadian Sulphur Ore Company, Limited, of which Mr. A. Longwell is president, and A. B. Willmott, secretary and treasurer. The head office is 404 Lumsden Building, Toronto, and the mine address is Queensboro, Ontario.

‡‡Formerly Wellington Prospect.

(To be continued.)

## WANTED—AN INTELLIGENCE BUREAU

(By Our Special Correspondent.)

At a recent mining meeting a speaker directed attention to the position of Canada in nickel and silver. His reluctance to include asbestos among the "first raters" was probably due to the unpopularity of the theme. A writer to the Mineral Industry* says, in part, "A decision of the directors to default payment of the interest on their consolidated bonds came as no surprise to the public at the end of 1911. The asbestos market has been depressed, but the mines are in excellent condition." A writer to the Journal summarizes the state of affairs by affirming that the cause of the late depression was overproduction and the remedy lay in the hands of the producer.

There may be a considerable divergence of opinions regarding the reactionary causes of such a depression, but any movement tending to stimulate and maintain a healthy condition of the industry would be welcome and to this end I would suggest an Intelligence Bureau at Quebec, and including in its functions:

Publicity.—There is no doubt that the major portion of the ills of the past depression were due to lack of intelligent, unprejudiced information. Overcapitalization would otherwise not appear so reasonable, and the manipulator of spurious properties would have a less successful task.

The regular issuing of statistics relative to foreign production might serve a valuable end. There appears in the London Mining Journal notice of a movement to form a syndicate to better organize and regulate the Russian asbestos trade. Undoubtedly, Canadian asbestos stands first in quality and quantity of ore, but judicious foresight will be safe policy.

Director Brock some time ago drew attention to the need of an inventory of mineral claims. This work could well be undertaken by such a bureau, and could embrace the metal and non-metallic claims throughout the province.

Experiments.—There is at present a wide difference of opinion regarding the character of the machines necessary for milling asbestos fibre. A series of anthentic tests would assist in standardizing these machines. Tests might also be made to find new uses for asbestos. The manufacturer is probably in the best position to carry on such tests, as he is also in extending the market for new articles, but he is not as directly interested in the amount of asbestos used as the producer, i.e., it may be cement, blue or gray asbestos, so long as the sales total are satisfactory.

Local Conditions.—Bulletins issued regularly summarizing production and accumulation of stocks would be a means of regulating production. The producer is always averse to accumulating large stocks.

The labour market has been unsatisfactory during the past few years, and while the labour conditions are rather difficult, there is no doubt much could be done to improve this question to the interest of employee and employer.

Co-operation has long been a debated question. It is probably unnatural to expect co-operation between prosperous companies and those which are losing money. No doubt, however, many of the future interests of the industry will depend upon whether the producers will exert their power to protect the industry or allow competitive forces to undermine their advantages. The Bureau might assist in determining and indicating what course of procedure would be most beneficial.

## WORKMENS' COMPENSATION IN MICHIGAN.

By R. E. Hore.

During the past year most of the Michigan copper mining companies elected to operate under the provisions of the Employer's Liability and Workmen's Compensation Act of Michigan which became effective September 1st, 1912. The principles striven for in this Act are: Reasonable compensation at minimum cost for all accidents except the result of wilful fault, certainty of amount, certainty of payment, payment without litigation and prevention of accidents. Fixed sums are paid under the Act for any injury which incapacitates an employee for a period of not less than two weeks. Amounts of compensation to be paid in case of death of employee is determined by the extent to which his immediate relatives have been dependent for support on his earnings. If employee leaves dependents wholly dependent upon him, the compensation is a weekly payment of one-half his average weekly wages, but not more than $10 nor less than $4 a week for 300 weeks. For complete disability the compensation is at the same rate for 500 weeks, the total not to exceed $4,000.

The compensation for partial disability is provided for as follows:

"While the incapacity for work resulting from the injury is partial, the employer shall pay, or cause to be paid as hereinafter provided, to the injured employee a weekly compensation equal to one-half the difference between his average weekly wages before the injury and the average weekly wages which he is able to earn thereafter, but not more than ten dollars a week; and in no case shall the period covered by such compensation be greater than three hundred weeks from the date of the injury. In cases included by the following schedule the disability in each such case shall be deemed to continue for the period specified, and the compensation so paid for such injury shall be as specified therein, to wit:

"For the loss of a thumb, fifty per centum of the average wages during sixty weeks;

"For the loss of a first finger, commonly called index finger, fifty per centum of average weekly wages during thirty-five weeks;

"For the loss of a second finger, fifty per centum of average weekly wages during thirty weeks;

"For the loss of a third finger, fifty per centum of average weekly wages during twenty weeks;

"For the loss of a fourth finger, commonly called little finger, fifty per centum of average weekly wages during fifteen weeks;

"The loss of the first phalange of the thumb, or of any finger, shall be considered to be equal to the loss of one-half of such thumb, or finger, and compensation shall be one-half the amounts above specified;

"The loss of more than one phalange shall be considered as the loss of the entire finger or thumb; Provided, however, that in no case shall the amount received for more than one finger exceed the amount provided in this schedule for the loss of a hand;

"For the loss of a great toe, fifty per centum of average weekly wages during thirty weeks;

"For the loss of one of the toes other than a great toe, fifty per centum of average weekly wages during ten weeks;

"The loss of the first phalange of any toe shall be considered to be equal to the loss of one-half of such toe, and compensation shall be one-half of the amount above specified;

"The loss of more than one phalange shall be considered as the loss of the entire toe;

"For the loss of a hand, fifty per centum of average weekly wages during one hundred and fifty weeks;

"For the loss of an arm, fifty per centum of average weekly wages during two hundred weeks;

"For the loss of a foot, fifty per centum of average weekly wages during one hundred and twenty-five weeks;

"For the loss of a leg, fifty per centum of average weekly wages during one hundred and seventy-five weeks;

"For the loss of an eye, fifty per centum of average weekly wages during one hundred weeks;

"The loss of both hands, or both arms, or both feet, or both legs, or both eyes, or of any two thereof, shall constitute total and permanent disability."

As stated by the accident industrial board, the theory of the compensation law is based on the assumption that when a worker is injured in an industry, the loss to him was occasioned by the industry, and that the product of that industry should be charged with his losses, and should pay for them. The law should be supported to the end that injured workmen may receive justice, that employers may have fixed liabilities and escape the embarrassment and expense of damage suits, that the courts be relieved of the time of trying damage suits, that the public treasury be relieved of the expense of caring for the victims of industrial accidents, that more harmonious relations be promoted between employers and employees.

In the past those injured in Michigan copper mines have been, for the most part, taken care of by benefit associations. For the year 1910 twelve copper mining companies reported a total of 53 fatal and 4,212 non-fatal accidents. The injured received from benefit associations, $87,133.75; directly from employers, $4,-523.45 and by settlements out of court, $5,418.00.

## THE EIGHT HOURS ACT.

An Act to amend The Mining Act of Ontario in respect to the House of Underground Employment.

HIS MAJESTY, by and with the advice and consent of the Legislative Assembly of the Province of Onario, enacts as follows:—

1. The Mining Act of Ontario is amended by inserting therein the folowing section:—

159.—(1) No workman shall remain or be allowed to remain underground in any mine for more than eight hours in any consecutive twenty-four hours, where the employer obtains from the Inspector a certificate that the means and methods in use at the mine of getting to and from the place of work in the mine are proper and satisfactory, shall be reckoned from the time of arriving at such place of work until the time of leaving such place, otherwise such eight hours shall be reckoned from the time of leaving the surface until the time of returning to the surface, or in such other way as the Inspector may direct; provided, however, that

(a) Time taken for lunch, not exceeding one half hour, need not be reckoned as part of such eight hours;

(b) A Saturday shift may work longer hours for the purpose of avoiding work on Sunday or changing shift at the end of the week or giving any of the men a part holiday.

(c) The said limit of time shall not apply to shift bosses, pump men, or persons engaged solely in surveying or measuring, nor shall it apply in cases of emergency where life or property is in imminent danger, or in any case of repair work, or to any mine where the number of men working in a shift does not exceed six.

(2) In this section

"Workman" means any person employed underground in a mine who is not the owner or agent or an official of the mine.

"Shift" means any body of workmen whose hours for beginning and terminating work in the mine are the same or approximately the same.

(3) Where any question or dispute arises as to the meaning or application of paragraph (c) of sub-section 1, or as to the meaning of "workman," "shift," or "underground," the certificate of the Inspector shall be conclusive.

(4) For greater certainty it is hereby declared that sections 174, 175, 179, 180 and 181 of this Act shall apply to contraventions of this section; provided, however, that a workman shall not be guilty of an offence for failure to return to the surface within the time limited by this section if he proves that without fault on his part he was prevented from returning owing to means not being available for the purpose.

(5) In the event of great emergency or grave economic disturbance, the Lieutenant-Governor in Council may suspend the operation of this section to such extent and for such period as he deems fit; or upon the Inspector certifying as regards any iron mine that the precautions, safeguards, and arrangements for protecting the health, safety and comfort of the workmen employed therein are satisfactory and in compliance with this Act, the Lieutenant-Governor in Council may, upon the recommendation of the Minister, in like manner suspend the operation of this action in so far as such mine is concerned.

(6) This section shall come into effect on the first day of January, 1914.

---

# ANNUAL REPORT OF HOLLINGER GOLD MINES LIMITED

## GENERAL MANAGER'S REPORT

The President and Directors,
Hollinger Gold Mines, Limited.

Dear Sirs.—

I beg to submit my second annual report, covering operations for the year 1912.

### FINANCIAL.

Operations were considered to begin July 1st, when the mill went regularly into commission, and all expenditures previous to that date were charged to "Plant" and "Development."

The sale of the balance of treasury stock (50,000 shares), at a premium of $5.00 per share, enabled all indebtedness to be cleared, and left the Company in possession of its mine and mill, fully paid for and in a productive condition.

Profits of $600,664.42 were earned during the last half of the year, in spite of the facts that mine and mill had to be worked up to a condition of smooth running, and that the last six weeks of the year were entirely devoted to fighting a labour strike.

As shown by the balance sheet, substantial amounts were written off from both "Plant" and "Development." It is well to point out that while "Development" stood at $302,639.19 there was an additional sum of $192,333.52 which had been actually expended by the original syndicate in development and upon road building, but which sum was not chargeable upon this Company's books. In fact, "Development," up to July 1st, 1912, had cost $494,972.71, so that the asset of $180,000.00, which is carried forward to 1913, represents a very conservative valuation; this with the carrying forward of plant at $500,000.00, after writing off $106,223.54 for depreciation, leaves the Balance Sheet with no fictitious values ascribed to assets, and with a surplus of $351,801.69, largely made up of cash, bullion and convertible sundries.

### THE MINE.

The following work was accomplished during theyear:

| | Drifts. | Crosscuts. | Winzes. | Raises. | Shafts. | Stopes. |
|---|---|---|---|---|---|---|
| 100-ft. level | 1,802 ft. | 401 ft. | 121 ft. | 60 ft. | ..... | 23,973 tons |
| 200-ft. level | 1,299 ft. | 820 ft. | 203 ft. | 90 ft. | 66 ft. | 6,767 tons |
| 300-ft. level | 179 ft. | 160 ft. | ...... | ..... | ..... | .......... |
| Totals | 3,280 ft. | 1,381 ft. | 324 ft. | 150 ft. | 66 ft. | 30,740 tons |

The total advance of workings amounted to 5,201 feet. Our underground workings now total 8,918 feet, distributed as follows:

| | Drifts. | Crosscuts. | Winzes. | Raises. | Shafts. |
|---|---|---|---|---|---|
| 100-ft. level | 3,141 ft. | 1,508 ft. | 224 ft. | 142 ft. | 362 ft. |
| 200-ft. level | 1,719 ft. | 1,096 ft. | 227 ft. | 90 ft. | 70 ft. |
| 300-ft. level | 179 ft. | 160 ft. | ...... | ...... | ...... |
| Totals | 5,039 ft. | 2,764 ft. | 451 ft. | 232 ft. | 432 ft. |

## DIAMOND DRILLING.

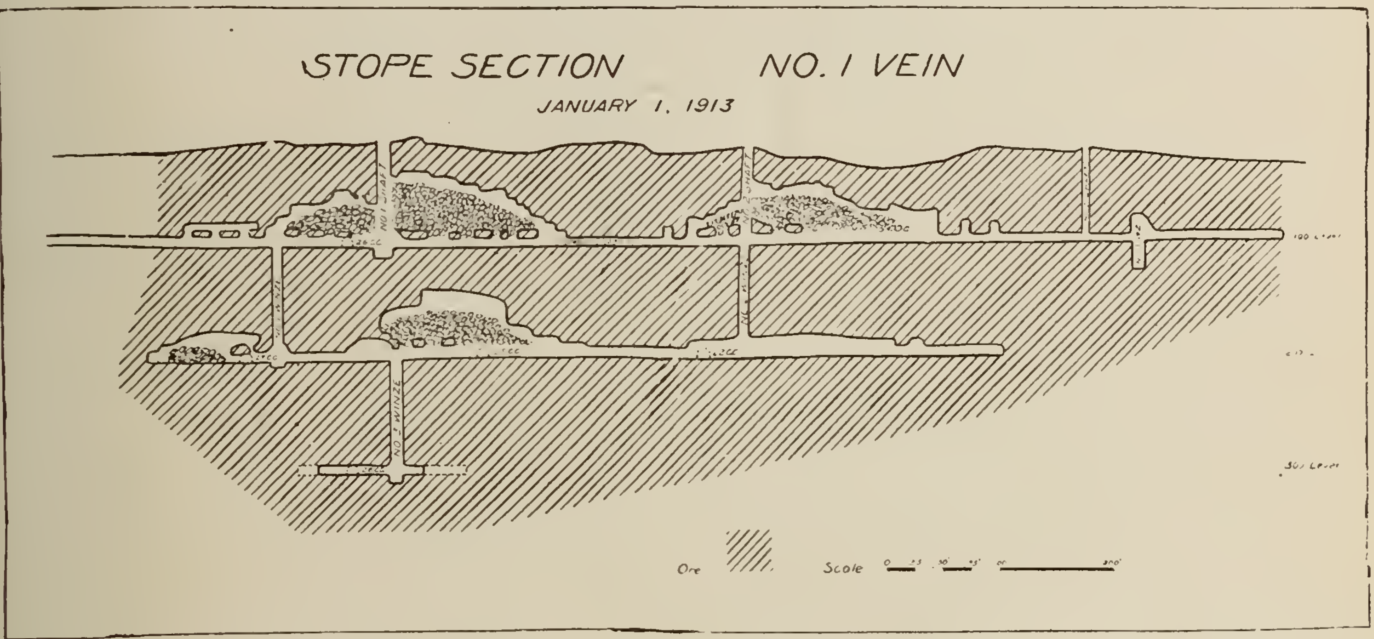
Prospecting by means of a diamond drill has been carried on with beneficial results, the amount of drilling being as follows:

| | |
|---|---|
| 100-ft. level | 588 ft. |
| 200-ft. level | 800 ft. |
| 300-ft. level | 78 ft. |
| Total | 1,466 ft. |

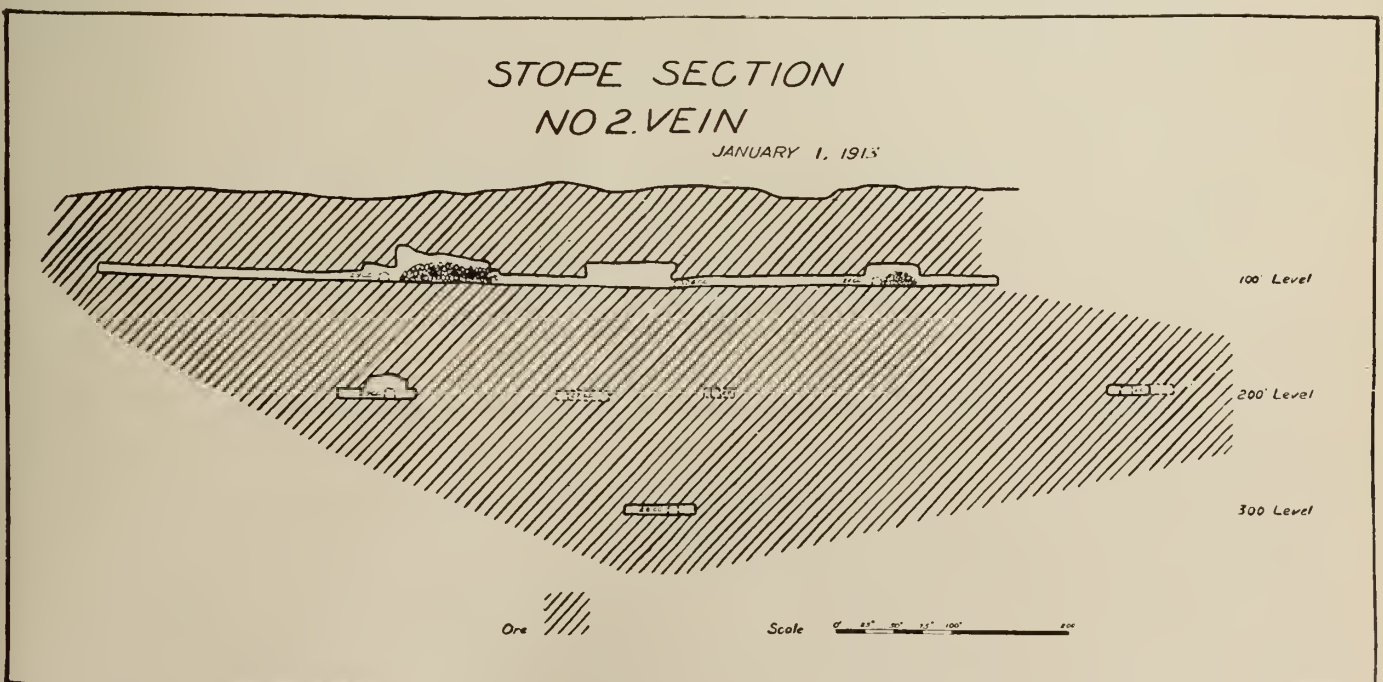
## ORE RESERVES.

Estimates of ore reserves are based upon the results of development, as shown upon the accompanying "Stope Sections" and plan.

Making allowances, as shown in the stope sections, the indicated ore reserves are estimated to be:



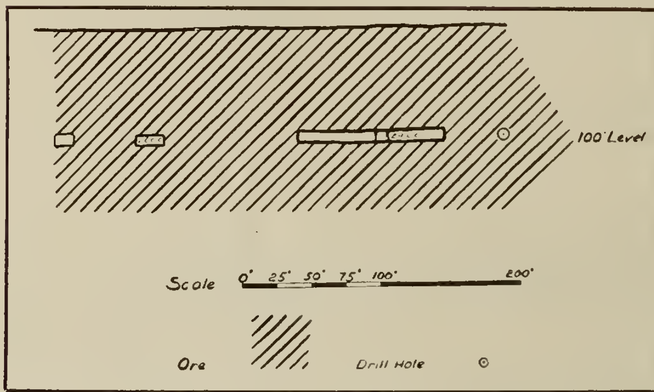
| Number 1 Vein— | Tons. | Value. |
|---|---|---|
| Above 100-ft. level | 42,700 | $1,229,700.00 |
| Above 200-ft. level | 78,700 | 2,560,800.00 |
| Above 300-ft. level | 75,400 | 1,960,400.00 |
| Below 300-ft. level | 12,000 | 275,200.00 |
| Total | 208,800 | $6,026,100.00 |



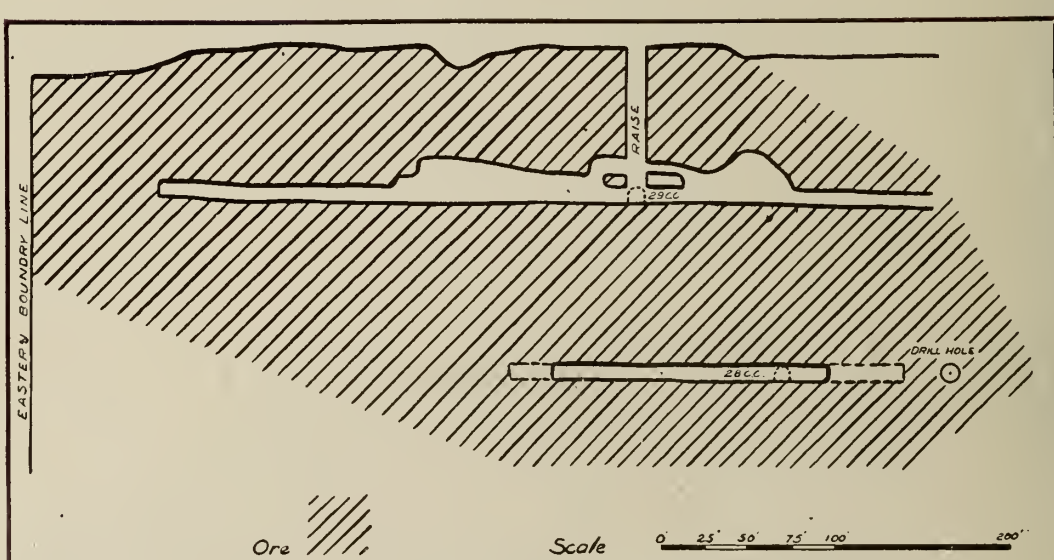
| Number 2 Vein— | Tons. | Value. |
|---|---|---|
| Above 100-ft. level | 48,560 | $ 672,480.00 |
| Above 200-ft. level | 76,800 | 1,025,970.00 |
| Above 300-ft. level | 65,780 | 829,700.00 |
| Below 300-ft. level | 10,660 | 120,100.00 |
| Total | 201,800 | $2,648,250.00 |

STOPE SECTION No. 3 VEIN

*January 1, 1913*



| Number 3 Vein— | Tons. | Value. |
|---|---|---|
| Above 100-ft. level..... | 13,650 | $102,000.00 |
| Below 100-ft. level..... | 8,950 | 67,000.00 |
| Total........... | 22,600 | $169,000.00 |

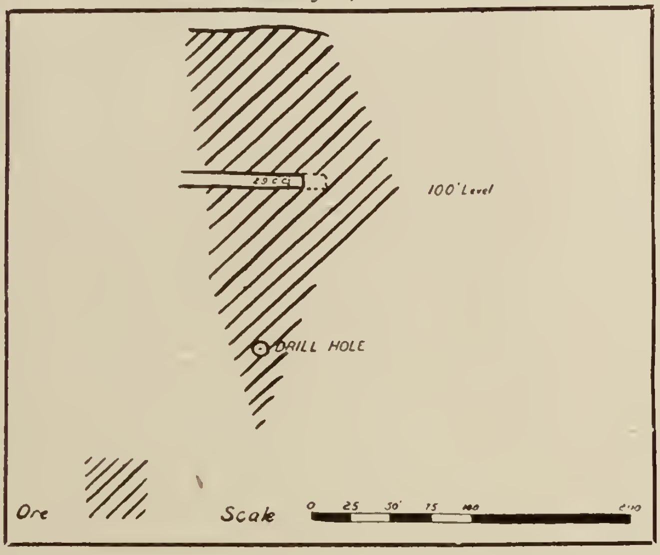


**Stope Section, No. 4 Vein.**

January 1, 1913.

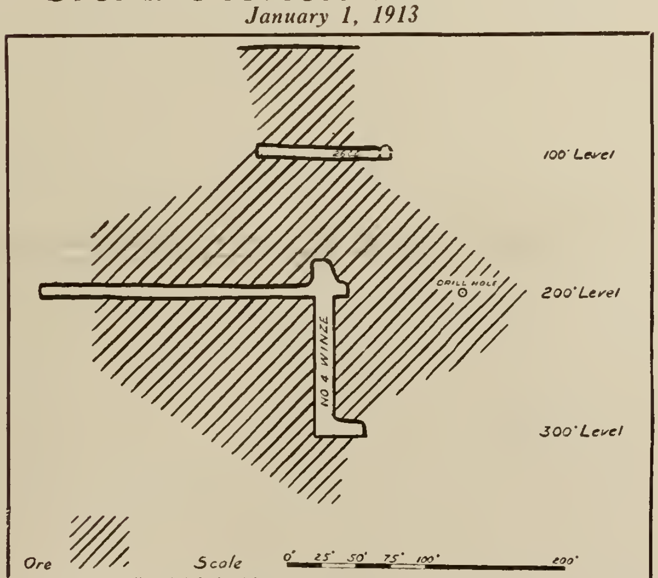
| Number 4 Vein— | Tons. | Value. |
|---|---|---|
| Above 100-ft. level..... | 31,800 | $ 378,800.00 |
| Above 200-ft. level..... | 40,700 | 502,200.00 |
| Below 200-ft. level..... | 11,800 | 131,000.00 |
| Total........... | 84,300 | $1,012,000.00 |

STOPE SECTION No. 8 VEIN
January 1, 1913



| Number 8 Vein— | Tons. | Value. |
|---|---|---|
| Above 100-ft. level..... | 4,920 | $49,200.00 |
| Below 100-ft. level..... | 4,580 | 27,950.00 |
| Total............ | 9,500 | $77,150.00 |

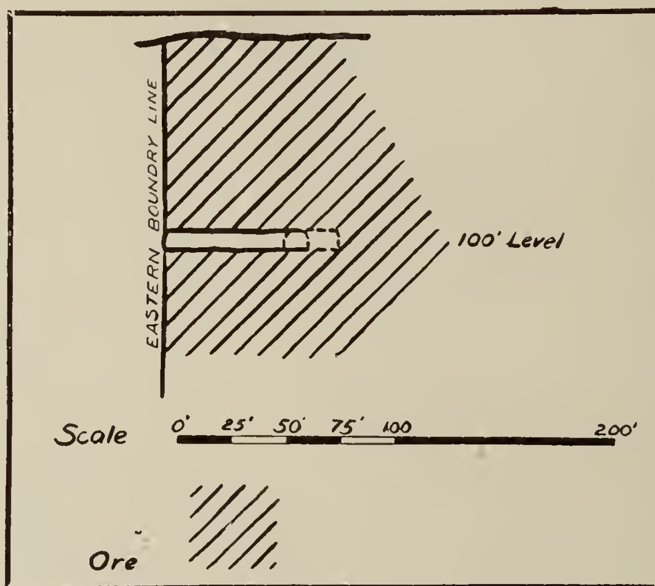
STOPE SECTION No. 37 VEIN
January 1, 1913



| Number 37 Vein— | Tons. | Value. |
|---|---|---|
| Above 100-ft. level..... | 3,960 | $ 39,600.00 |
| Below 100-ft. level..... | 13,240 | 150,900.00 |
| Above 200-ft. level..... | 13,600 | 190,400.00 |
| Below 200-ft. level..... | 2,000 | 20,000.00 |
| Total............ | 32,800 | $400,900.00 |

## STOPE SECTION No. 38 VEIN

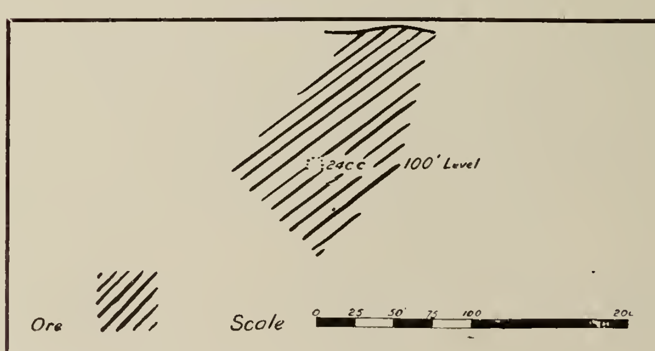
*January 1, 1913*



| Number 38 Vein— | Tons. | Value. |
|---|---|---|
| Above 100-ft. level..... | 5,000 | $ 77,500.00 |
| Below 100-ft. level..... | 3,100 | 46,500.00 |
| Total............ | 8,100 | $124,000.00 |

## STOPE SECTION No. 40 VEIN

*January 1, 1913*



| Number 40 Vein— | Tons. | Value. |
|---|---|---|
| Above 100-ft. level..... | 3,220 | $58,600.00 |
| Below 100-ft. level..... | 1,220 | 22,200.00 |
| Total............ | 4,440 | $80,800.00 |
| Number 41 Vein— | | |
| Above 200-ft. level..... | 1,100 | $16,600.00 |
| Below 200-ft. level..... | 1,000 | 16,600.00 |
| Total............ | 2,200 | $33,200.00 |

**RECAPITULATION OF ORE RESERVES.**

| | Tons. | Value. | Estimated at Beginning of 1912. |
|---|---|---|---|
| No. 1 Vein...... | 208.800 | $6.026.100.00 | $7,560,000.00 |
| No. 2 Vein...... | 201.800 | 2.648.250.00 | 1.200.000.00 |
| No. 3 Vein...... | 22.600 | 169.000.00 | 150,000.00 |
| No. 4 Vein...... | 84.300 | 1,012.000.00 | 450,000.00 |
| No. 8 Vein...... | 9.500 | 77,150.00 | 140,000.00 |
| No. 37 Vein...... | 32.800 | 400.900.00 | ......... |
| No. 38 Vein...... | 8.100 | 124,000.00 | ......... |
| No. 40 Vein...... | 4.440 | 80,800.00 | ......... |
| No. 41 Vein...... | 2,200 | 33.200.00 | ......... |
| Veins 5, 7, 9, 11, 12, 13, 14, 23, 33, 35, 36, 39, 42 and 43........ | 70.000 | 700.000.00 | 730,000.00 |
| Totals...... | 644.540 | $11.271,400.00 | $10,230,000.00 |

The total value estimated in my report of a year ago was $10,230,000.00, and during the time between reports we have milled $970,304.89 from the previously estimated reserves.

The year has been spent in proving up previous estimates, and it will be noted that, with the exception of Number 1 Vein and Number 8 Vein, there is a general increase in the values ascribed to the various ore bodies.

The original reserves of No. 1 Vein were estimated upon the basis of a solid block of ore 300 feet in depth, while the present estimate is based upon more extensive development and does not include so large a block of ore as was included in last year's figure. Further, during 1912, approximately $760,000.00 was removed from the estimated reserves of No. 1 Vein.

We are now assured of the prevalence of ore to a depth of 300 feet, and there is no known reason why it should not be found at considerably greater depths, but in order to become established upon a conservative basis, no allowance has been made for ore which may exist beyond a depth of 50 feet below the deepest working of any vein.

Compared with a year ago, our position in the matter of ore reserves has been greatly strengthened, for our present estimates are the result of development work, and the estimated values per ton have been substantiated by the milling of 45.195 tons of ore.

There are 34 known veins upon which no work has been done, other than sampling the surface outcrops. As in last year's report, these are included in ore reserves at arbitrary nominal figures.

Veins 37, 38, 39, 40, 41, 42 and 43 are new discoveries made during the year.

In last year's estimates, No. 8 Vein was figured to a depth of 200 feet, while this year it is figured to a depth of 150 feet, the reduction being made in accord with the policy of limiting estimates to a depth of 50 feet below the workings.

In the mine there are 24 faces which carry ore and which are available as working places. They are:

100-foot level—
- No. 2 Vein, south of 26 crosscut.
- No. 3 Vein, south face.
- No. 3 Vein, north face.
- No. 3 Vein, south of 26 crosscut.
- No. 8 Vein, south face.
- No. 38 Vein, south of 30 crosscut.

200-foot level—
- No. 1 Vein, south face.
- No. 1 Vein, north face.
- No. 2 Vein, south of 29 crosscut.
- No. 2 Vein, north of 29 crosscut.
- No. 2 Vein, south of 27 crosscut.
- No. 2 Vein, south of 26 crosscut.
- No. 2 Vein, north of 26 crosscut.
- No. 2 Vein, south of 22 crosscut.
- No. 2 Vein, north of 22 crosscut.
- No. 4 Vein, north of 28 crosscut.
- No. 4 Vein, south of 28 crosscut.
- No. 37 Vein, south of 26 crosscut.

300-foot level—
- No. 1 Vein, north face.
- No. 1A Vein, south face.
- No. 1 Vein, south face.
- No. 2 Vein, north face.
- No. 2 Vein, south face.
- No. 37 Vein, north face.

In addition to this work there is a large amount of crosscutting to do, besides the necessary raises and winzes for development.

There is also the opening up of various groups of veins which have been exposed upon the surface, but which are too far removed to be reached expeditiously from the main workings.

Altogether there is room for from 25 to 30 drills to be used upon development work alone. This, in conjunction with the drills required for stoping ore to feed the mill, creates a demand for compressed air sufficient to operate about 55 drills, and there is the further demand for air with which to operate hoists, pumps and diamond drills.

The foregoing is given by way of explaining why we have not made more headway in sinking to greater depths. The opening up of the mine upon the upper levels has at all times demanded air in excess of the capacity of our plant.

The electrical apparatus for driving our 14-drill compressor having been destroyed by fire, it was not until the middle of February that this could be replaced, and until that time we had but a small 6-drill machine in operation.

Subsequently another 15-drill compressor was placed at work and a third machine of this size has just been installed upon the adjoining Dixon claim; the surplus air from this latter compressor will be available for use in the Hollinger mine.

The temporary equipment of compressors now installed will serve for the present, and meanwhile a central air compressing plant is being planned which will be of a permanent nature and of sufficient capacity to supply future requirements.

From November 15th to the end of the year, work in the mine was at a standstill, owing to the labour troubles which unexpectedly arose, this cessation resulting in a further reduction in the amount of work accomplished during the year.

The ore hoisted during the year amounted to 36,446 tons. All of this, together with ore previously placed upon the dump, was milled, the total amounting to 45,195 tons and containing $970,304.89, of which amount $933,681.53 was recovered. In the total values recovered, silver amounted to $6.546.93 and gold $927,134.60.

The average value of all ore treated was $21.44 per ton, including the low grade ore sent to the mill at the commencement of millin goperations, and that milled during the strike.

We have now recovered sufficiently from the effects of the strike to enable sinking operations to be resumed, and we propose to continue No. 3 Winze to the 400-foot level at once.

The raising of the main shaft from 300 to 200-foot level will also be undertaken at once, and when this is completed the shaft will be continued down to 400 feet.

## THE MILL.

The first stamps were dropped June 15th and for two weeks nothing was treated but waste rock and very low grade ore, until the usual mechanical defects, incident to a new mill, were made right.

Early in July, cyaniding was commenced and the mill was put into regular operation. Beginning with June 15th, the following tonnages were treated, the figures being for four-week periods:

| | Tons Treated. | Values Recovered. |
|---|---|---|
| June 15—July 13 | 4,447 | $ 23,129 |
| July 14—Aug. 10 | 6,132 | 152,437 |
| Aug. 11—Sept. 7 | 7,606 | 171,634 |
| Sept. 8—Oct. 5 | 7,905 | 197,657 |
| Oct. 6—Nov. 2 | 8,012 | 189,685 |
| Nov. 3—Nov. 30 | 6,335 | 122,931 |
| Dec. 1—Dec. 31 | 4,758 | 76,209 |
| Totals | 45,195 | $933,682 |

It will be noted that up to November, steady progress was made toward increasing both tonnages and values of ore treated.

November and December showed a falling off due to the strike.

The mill has operated in a satisfactory manner, and experience has demonstrated that the process adopted is the correct one for the treatment of Hollinger ores.

Originally our practice was to amalgamate concentrates in pans, in order to remove the contained values, but after several months of experimenting, amalgamation was abandoned in favour of the cyanidation of the concentrates. This necessitated no change in apparatus, the substitution of potassium cyanide for mercury, in the grinding pans, being all that was required.

The agitators which were adopted at the start did not prove to be adapted to the handling of our heavy ores, and we have therefore discarded the Trent apparatus in favour of Dorr Thickeners. For the benefit of the uninitiated it may be stated that the above change merely involves the substitution of one type of stirring arms for another, in an ordinary round tank.

By the substitution of the Dorr mechanism we are enabled to practice continuous decantation, which is expected to result in an increased saving of dissolved values, and may possibly enable a considerable saving in treatment charges to be made by making it possible to do away with the comparatively expensive item of filtering.

It was intended to make these changes before the end of last year, but our plans were upset by labour troubles and it is not expected that the work will be completed before May 1st.

## WORKING COSTS.

The year's work having been so badly deranged, statistical data in regard to costs would be meaningless.

It will be some months before work in the various departments will be brought up to a state of efficiency, but the costs for February, 1913, are given, as they are indicative of what may be expected, although they are inordinately high.

## MINING COSTS.

### Four Weeks Ending February 25th, 1913.

| Account— | Labour. | Stores. | Total. | Per Ton of Ore Milled. |
|---|---|---|---|---|
| General Mining Charges | $ 363.31 | $ 124.02 | $ 487.33 | $0.053 |
| Superintendence | 1,160.95 | ...... | 1,160.95 | .126 |
| Diamond Drilling | 162.97 | 87.72 | 250.69 | .027 |
| Crosscutting | 145.34 | 255.61 | 400.95 | .043 |
| Drifting | 1,868.54 | 1,256.84 | 3,125.38 | .338 |
| Raising | 43.86 | 21.16 | 65.02 | .007 |
| Stoping | 7,895.77 | 6,709.53 | 14,605.30 | 1.581 |
| Timbering Stopes | 1,837.06 | 183.73 | 2,020.79 | .219 |
| Track Laying | 70.06 | 50.20 | 120.26 | .013 |
| Tramming and Mucking | 4,042.04 | 6.34 | 4,048.38 | .438 |
| Pipe Fitting Underground | 133.40 | 256.83 | 390.23 | .042 |
| Mine Drainage | 130.71 | 335.53 | 466.24 | .050 |
| Hoisting | 837.27 | 734.21 | 1,571.48 | .170 |
| Landing and Dumping | 583.38 | ...... | 583.38 | .063 |
| Drill Repairs | 138.67 | 847.67 | 986.34 | .107 |
| Drill Sharpening | 1,262.30 | 36.48 | 1,298.78 | .141 |
| Distributing Steel | 460.03 | ...... | 460.03 | .050 |
| Mine Sampling | 372.33 | 8.60 | 380.93 | .041 |
| Assaying | 72.81 | 80.11 | 152.92 | .017 |
| Change House | 70.00 | ...... | 70.00 | .008 |
| Mine Lighting | 30.49 | 15.94 | 46.43 | .005 |
| Handling Explosives | 227.90 | 3.87 | 231.77 | .025 |
| Handling Waste | 147.75 | ...... | 147.75 | .016 |
| Surveying | 76.47 | ...... | 76.47 | .008 |
| | $22,133.41 | $11,014.39 | $33,147.80 | $3.588 |

## MILLING COSTS.

**Four Weeks Ending February 25th, 1913.**

| Account— | Labour. | Stores. | Total. | Per Ton of Ore Milled. |
|---|---|---|---|---|
| General Milling Charges | $1,117.98 | $ 357.18 | $1,475.16 | $0.160 |
| Superintendence | 694.94 | ...... | 694.94 | .075 |
| Tailings Disposal | ...... | 1.72 | 1.72 | .... |
| Heating | 384.92 | 314.78 | 699.70 | .076 |
| Lighting | 24.50 | 161.63 | 186.13 | .020 |
| Watchman | 79.80 | ...... | 79.80 | .009 |
| Sampling | 55.53 | .40 | 55.93 | .006 |
| Assaying | 145.62 | 160.23 | 305.85 | .033 |
| Coarse Crushing | 410.66 | 264.00 | 674.66 | .073 |
| Conveying | 221.17 | 92.35 | 313.52 | .034 |
| Stamping | 786.30 | 885.94 | 1,672.24 | .181 |
| Classification and Tube Milling* | 491.06 | 2,067.91 | 2,558.97 | .277 |
| Concentration | 415.11 | 113.67 | 528.78 | .057 |
| Handling Concentrates | 28.84 | 86.66 | 115.50 | .012 |
| Grinding Concentrates | 158.83 | 170.87 | 329.70 | .036 |
| Handling Pulp | 71.78 | 131.09 | 202.87 | .022 |
| Thickening | 91.03 | 19.35 | 110.38 | .012 |
| Agitation | 103.62 | 167.68 | 271.30 | .029 |
| Filtration | 908.46 | 448.35 | 1,356.81 | .147 |
| Acid Washing | 27.08 | 92.00 | 119.08 | .013 |
| Neutralizing | 109.56 | 100.50 | 210.06 | .023 |
| Clarification and Precipitation | 107.42 | 576.51 | 683.93 | .074 |
| Smelting and Retorting | 151.16 | 432.97 | 584.13 | .063 |
| Pumping Solutions | 115.14 | 72.01 | 187.15 | .020 |
| Cyanide | ...... | 381.22 | 381.22 | .041 |
| | $6,700.51 | $7,099.02 | $13,799.53 | $1.493 |
| Extraordinary Expenditures (alterations) | 953.60 | 891.33 | 1,844.93 | .200 |
| | $7,654.11 | $7,990.35 | $15,644.46 | $1.693 |

*Classification and tube milling include the cost of repairing the linings of three tube mills.

## TOTAL OPERATING COSTS.

**Four Weeks Ending February 25th, 1913.**

| | Amount | Per Ton of Ore Milled |
|---|---|---|
| Administration, Management, Insurance, etc. | $ 3,763.54 | $0.407 |
| General Charges | 1,931.08 | .209 |
| Clearing Surface, Roads, etc. | 137.75 | .015 |
| Mining | 33,147.80 | 3.588 |
| Milling | 13,799.53 | 1.493 |
| Operating Camp | 2,415.96 | .261 |
| Extraordinary Expenditures | $55,195.66 | $5.973 |
| Loss on Temporary Boarding Houses | 384.70 | .042 |
| Alterations to Mill and Plant | 2,034.51 | .221 |
| Strike Expense | 4,695.37 | .508 |
| | $62,310.24 | $6.744 |

Mining costs are admittedly high. We are working with a force of men collected hurriedly in outside camps and brought in to replace the men who went out on strike, and this new force has not yet reached a high state of efficiency. A gradual reduction in mining costs may be expected.

Milling costs are high owing to abnormal expenditures for alterations and repairs.

Geenral costs are greatly increased by the extraordinary expenses incurred in providing protection against strikers, in quatering employees upon the mine, and inefficiency engendered by existing conditions.

Further, the figures given are for a period in midwinter, when costs of heating the camp and works are a heavy item of expense.

Substantial reductions in working costs may therefore be looked for, and it is expected that with uninterrupted working, the total costs will be brought down to approximately $5.50 per ton.

### GENERAL.

The work of the year progressed satisfactorily until November 15th, upon which date the Western Federation of Miners declared a strike, and by intimidation forced about one-half of our men to go out.

There had been no dispute between the Company and its men, and the strike was entirely unexpected.

The strike was gneral throughout the camp and was unsuccessful.

We were forced to abandon our boarding houses in the Town of Timmins and put up temporary quarters at the mine. It was also necessary for us to bring in a number of special police to protect our men and property.

The men who remained loyal enabled us to keep the mill going, and our force was gradually built up by men coming in from outside camps.

The working conditions are better here than elsewhere in Ontario. We pay from $3.25 to $3.75 per day for skilled labour, and from $2.50 to $3.00 for unskilled. Bed and board are furnished for 60 cents per day. Nine hours constitutes a day's work in the mine, and eight-hour shifts are worked in the mill.

The strike has gradually dwindled until there are now (March 19th) 1,200 men at work in the camp, of which number approximately 500 are employed by this Company.

Some 150 men are actively engaged in trying to interfere with those who wish to work. This small number of malcontents is largely made up of professional agitators surrounded by a following of incompetents who have availed themselves of the opportunity to put in a winter of idleness, meanwhile being supported and fed by donations received from outside labor organizations.

It is hoped that the Government will rid the district of this undesirable element.

Directly and indirectly the tsrike has cost the Company fully $100,000.00, besides the intangible loss due to the disorganization of all departments.

### HOSPITAL.

A comfortable hospital has been provided by Canadian Mining & Finance Co., Ltd., in the Town of Timmins, the use of which is open to employees of the Hollinger mines.

### BUNK HOUSES.

Up to the present the only bunk houses available have been those provided by Canadian Mining & Finance Co., Ltd., but we are now constructing three bunk houses at the mine which will accommodate 150 men in ordinary times, and which may be used for 300 men in times of emergency. These are to have plastered rooms, two men in a room.

Ten cottages for married men have been built in the town. It is possible that we may find it necessary to increase this number.

### POWER SUPPLY.

Electric power developed from hydro-electric plants upon the Mattagami River has proved entirely satisfactory. The action of the directors in disposing of their holdings in the plant at Sandy Falls, in order to bring about a consolidation with the company operating Waiwaiten Falls, has made available two independent sources of power.

The two plants being distant twenty-eight miles from one another, makes a failure in power supply practically impossible either from accident or shortage of water.

### ACCIDENTS.

There is but one fatality to report as occurring during the year. A. Lahte, a miner, was instantly killed on January 9th by the blowing up of a dynamite thawing house; cause unknown.

Before closing, I wish to record my appreciation of the loyal services rendered by the Company's staff and men during the recent labour disturbances, and to thank the directors for their support during the year.

Yours truly,

P. A. ROBBINS,

General Manager.

## INTERNATIONAL COAL AND COKE COMPANY

The ninth annual report of the International Coal and Coke Co., operating coal mines and coke ovens ot Coleman, southwest Alberta, covers the calendar year ended Dec. 31, 1912. It shows a net profit of $232,198 for the 12 months, of which $132,198 was transferred to the surplus account and $100,000 has been carried forward into the working and dividend fund for the current year. The company's liabilities were reduced $139,318 and the assets were increased $92,880, while the payroll amounted to $563,906, expended during the 254 days the mines were operating, employing an average of 520 men daily. The expenditures for development, additions to plant and other necessary outlay aggregated $61,342.

The assets of the company total $3,987,443, segregated as follows: Coal lands, $3,135,955; plant, dwellings, horses, etc., $658,817; warehouse stock, $27,890; accounts receivable, $165,753; stocks of coal and coke, $2,173; unexpired insurance, $1,682; cash on hand, $172.

At the annual meeting of the company, held in Spokane, Washington, last month, the question of paying dividends quarterly was discussed. While nothing definite was decided, the secretary informed shareholders that if nothing shall occur to interrupt coal-mining operations the payment of a regular quarterly dividend might be expected.

The officers of the company are: President, Mr. A. C. Flumerfelt, Victoria, B.C.; first vice-president, Mr. Hugh Davidson, Vancouver, B.C.; second vice-president, Mr. D. H. Kizer, Spokane; treasurer, Mr. John McKeagan, Coleman, Alberta; secretary, Mr. W. G. Graves, Spokane; managing director, Mr. P. W. Riddell, Coleman; manager, Mr. O. E. S. Whiteside.

## MINE ACCIDENTS

Speaking before a large number of men employed in and about the coal mines of the Western Fuel Co., near Nanaimo, Vancouver island, B.C., Mr. Thomas Graham, chief inspector of mines for British Columbia, after having given some accident and mortality statistics, said:

"Legislation, however stringent, or supervision, however efficient, will not prevent this class of accidents. Here, so much depends upon the personal element that only by the co-operation of every person concerned, from the mine inspector and the manager down to the trapper boy, can it be hoped to reduce to a minimum the number of accidents from falls of roof and coal. At such a meeting as we have to-night, at which are present so many fire-bosses and shot-lighters, it is an opportune time to urge upon them the great necessity that exists for their unremitting co-operation, for they come daily into closer contact with all underground employes than do other mine officials; so that an occasionals word of advice, warning or admonition from them is likely to do much toward reducing the number of fatal accidents from the causes just mentioned, as well as from haulage."

The occasion of Mr. Graham's remarks was the meeting of the Western Branch of the Canadian Mining Institute, held at Nanaimo the first week in March, and these timely observations were made immediately before Mr. J. F. Menzies, of Roslyn, Washington, general superintendent of the Coal Department of the Northwestern Improvement Co., read a paper on "Mine-Rescue and First-Aid Work."

# WORK AT THE SENECA SUPERIOR MINE, PETERSON LAKE, COBALT

[Editor's Note.—Under date of April 5th, 1913, the following information was kindly provided by the management of the Seneca Superior mine. It covers in part the work done in March.]

**Surface.**—Work has been progressing satisfactorily in all departments. The new rock house is completed and operating. The ore treating equipment, consisting of bumping table, Harz jig and Deister concentrating table, is all installed and running.

A fire pump was ordered and work begun on pump house on the edge of our dump. The new thaw house was completed and connected with the shore by a substantial bridge. Work was also started on a new dry house in place of the building originally built for the purpose and which has been used as a carpenter shop.

We have completed the tests on ore from the "mill dump," sending about sixty tons to both the Dominion Reduction Company and the Nipissing Reduction Company. The results were unsatisfactory, showing in one case an assay of 4.4 ounces to the ton, and in the other 7.7 ounces. This result bears out our previous opinion and indicates that the values of the ore, instead of being scattered in the wall rock, have been confined closely to the vein matter. Until such time as our assays indicate that the wall rock is showing better value we propose to dump same into the lake and thus save our dumping area on the surface.

**Shaft No. 2.**—Work was begun sinking this shaft and will be continued night and day to meet the up-raise from the 200-ft. level.

**Peterson Lake.**—Unwatering this property was begun on the twenty-fourth ult., and at this writing the water is below the first level. We expect to have the entire mine unwatered in another week.

**Underground.**—Timbering the drift, east and west, has been steadily proceeding and stoping the ore overhead. We have also been back stoping the vein in the east preparatory to cutting hitches and timbering.

Owing to air conditions we stopped work late in the month on the No. 3 X cut and No. 1 Drift East, confining the work to stoping and driving No. 2 Crosscut. We have ordered ventilating pipe, to run from the shaft to the Worth vein and expect to have same installed in a few days when active work will be resumed at all points. The advances made during the month totalled 146 feet 11 inches.

At this date the air conditions are greatly improved and it is likely that our troubles on that account are well over, as the snow is about gone and we are having some thawing weather.

**Seneca Superior Shaft House**

**Productions and Shipments.**—

| | High Grade. | Jig Concentrates. |
|---|---|---|
| On hand March 1st | 31,092 lbs. | |
| Produced during month | 42,534 lbs. | 3,685 lbs. |
| | 73,626 lbs. | |
| Add concentrates | 3,685 lbs. | |
| | 77,311 lbs. | |
| Shipped March 18th | 60,236 lbs. | |
| High grade on hand, March 31st | 17,075 lbs. | |

In addition to above we produced 41,760 lbs. screenings, but as they will be jigged and included in later concentrates, they are not included in above estimate.

Assuming the above shipping product of the month to assay 4,000 ounces to the ton, our total ounces produced, not counting the screenings and dump, amount to 46,219 lbs. x 4,000, or 92,438 ounces.

**Accounting.**—Expenses for the month were as follows:

| | |
|---|---|
| Accounts payable. . . . . . . . . . . . . . . . . . . . . | $5,350.39 |
| Pay roll. . . . . . . . . . . . . . . . . . . . . . . . . . . | 4,373.69 |
| | $9,724.08 |

or ten and one-half cents per ounce.

# PERSONAL AND GENERAL

Mr. Wm. Fowler, well-known in the Boundary Creek district, British Columbia, where he developed the Providence, a small but rich gold-silver mine situated near Greenwood, is now in Oregon.

Mr. Archibald Dick, now retired, but formerly senior inspector of mines in British Columbia, was at the C. M. I., Western Branch, meetings in Nanaimo last month, where he heard expressed much appreciation of the value of the report on "Mine-Rescue Work in Canada," by his son, Mr. W. J. Dick, M. Sc., mining engineer for the Canadian Commission of Conservation, which report had lengthy notice in the Canadian Mining Journal of February 1st.

Mr. George Watkin Evans, of Seattle, Washington, formerly geologist in charge of the coal surveys of the State of Washington Geological Survey, who presented at the C.M.I. branch meeting at Nanaimo last month a paper on the Groundhog coal field, British Columbia, with lantern-slide illustrations, is the author of the lately-issued Bulletin No. 3 of the Washington Geological Survey, which deals with the coal measures of King County, Washington.

Mr. Leslie Hill, for years resident in Nelson, B.C., having retired from the practice of his profession of mine manager and consulting engineer, has resigned his membership in the Canadian Mining Institute. He is now livng on his fertile land near Vernon, Okanagan Valley, one of the most productive fruit-growing districts in British Columbia.

Mr. A. B. W. Hodges, formerly local manager for the Granby Consolidated M. S. and P. Co., Ltd., and resident at Grand Forks, Boundary District, B.C., for eleven or twelve years, writing from Lima, Peru, to a friend in Victoria, B.C., on January 30th, gave the following information: As my three-years' contract as general manager of the Cerro de Pasco Mining Company will terminate at the end of February, I shall be leaving Peru permanently. I expect to travel in the Northwest for several months, and hope to see my friends in Victoria and Vancouver about next July or August.

Mr. James Holden has retired from the position of superintendent for the Princeton Coal and Land Company at Princeton, Similkameen, B.C., after having had charge of the development of the company's coal mine from a prospect to its present condition of being well-opened and equipped for the production and shipment of coal.

Mr. John Hopp, of Barkerville, Cariboo, was one of the several British Columbia members who attended the annual meeting of the Canadian Mining Institute at Ottawa last month. His hydraulic placer-gold mining operations are on the largest scale of all being carried on in the Cariboo district. He has been visiting some of the larger cities of the eastern United States and Canada, prior to returning west to resume hydraulicking operations as soon as the season shall be far enough advanced to admit of his doing so.

Mr. Thos. R. Jackson, formerly of No. 2 mine. Extension Colliery, Vancouver Island, and since then with the Western Fuel Company, Nanaimo, has been appointed superintendent of that company's new mine, known as Reserve Shaft, situated between four and five miles south of Nanaimo.

Mr. Andrew G. Larson has returned to Vancouver, B.C., from a short holiday visit to Los Angeles, Cal.

Mr. J. McLellan, one of the owners of a small gold mine, at Gold or Mitchell Harbour, on the west coasts of one of the Queen Charlotte Islands, B.C., has been in England. It was stated that it was his intention to visit Cobalt before returning to British Columbia.

Mr. F. Chas. Merry continues to have charge of the Silver Sup and Nettie L. groups of mines, in Trout Lake mining division, Lardeau district of British Columbia. Shpment of silver-lead ore from the former group has been maintained for a number of years, while during recent months some ore has also been sent out from the latter, after several years of inactivity and consequent non-production.

Mr. James Price, who after having worked thirty-seven years in the coal mines at Nanaimo—thirty-three years as a fire boss—has decided to "get back to the land" and spend his well-earned retirement on his "ranch," near Nanaimo, was last month the recipient of a valuable gold watch, presented to him by his fellow miners and the officials of the Western Fuel Company.

Mr. Thos. T. Read, of San Francisco, California, associate editor of Mining and Scientific Press, has been visiting several parts of Arizona.

Mr. Hallett R. Robbins, who several years ago was in charge of development work at a mining property, Hedley camp, Similkameen, B.C., and recently of Atlantic, Wyoming, has been appointed assistant professor in the Department of Mining Engineering and School of Mines, State College of Washington, Pullman, Washington, in place of the late Mr. Roswell E. Sampson, who was run over and killed by a railway train last winter.

Mr. Bruce White has returned to Nelson, B.C., from a visit to Boston and the State of Maine.

Hon. Dr. H. E. Young, provincial secretary in the McBride Government, British Columbia, has gone north to personally investigate the situation in connection with recent reports of new finds of placer-gold on creeks flowing into Teslin Lake, mention of which was made in the Canadian Mining Journal on January 15th last, page 48, and in connection with which there has lately been a little excitement at Atlin and other northern settlements.

Mr. W. Fleet Robertson, Provincial Mineralogist of British Columbia, who, during his stay in the East, has been conferring with the Executive Comimttee of the International Geological Congress with regard to the

British Columbia excursion arrangements, leaves for Victoria towards the end of March.

Mr. A. W. Allen, secretary of the Lucky Jim Zinc Mines, Limited, is now resident in Victoria, B.C., the company's office having been removed to that city from Kaslo, Kootenay Lake. Now that the interruption to railway traffic by frequent snow slides has ceased, shipment of zinc ore from the Lucky Jim mine, Slocan District, to the United States has been resumed by the company.

Mr. J. W. Boyle, of Dawson, Yukon Territory, was in London, England, in February. Another Yukon visitor to that country was Mr. A. N. C. Treadgold, also of Dawson, managing director of the Granville Mining Company.

Mr. E. E. Campbell, one of the Granby Consolidated M. S. and P. Company's mining engineers, is in Hazelton district, Skeena River country, British Columbia, obtaining information relative to prospective ore output, etc.

Mr. Norman Carmichael, formerly manager of the Duncan United Mines, in West Kootenay, B.C., and now general manager for the Arizona Copper Company, Limited, was at Globe, Arizona, recently. Mr. John Kiddie, elder son of Mr. Thos. Kiddie, the well-known metallurgist of British Columbia, now holds a prominent and responsible position under Mr. Carmichael and has his headquarters at Morenci.

Mr. Hayman H. Claudet, representative in British Columbia of the owners of the Elmore Vacuum process, small plants of which he has from time to time installed and operated in that province, recently left Rossland on a trip to Europe.

Mr. John F. Coats, of Spokane, Washington, who some time since had charge of development work at a coal property on Tulameen river, a few miles above Princeton, Similkameen, B.C., was one of the members of the Canadian Mining Institute who attended the meeting of the Western Branch held in Nanaimo, Vancouver Island, on March 4th and 5th.

Mr. Alex. Faulds, of Vancouver, B.C., was in Los Angeles, California, a short time ago.

Prof. T. S. McCaffery, of Moscow, Idaho, professor of mining engineering, University of Idaho, in his capacity of chairman of the Spokane Local Section of the American Institute of Mining Engineers, is interesting himself in promoting the success of the joint meeting of the section with the Western Branch of the Canadian Mining Institute, to be held at Rossland, B.C., in May, proximo.

Mr. J. W. D. Moodie, of Britannia Beach, Howe sound, B.C., vice-president and general manager of the Britannia Mining and Smelting Co., is busily engaged in pushing forward the work of extensive further development and equipment of the company's copper-mining property on Britannia mountain, and concentrating plant at Britannia Beach.

Mr. W. G. Norrie, of Bear lake, Slocan, B.C., superintendent for the Lucky Jim Zinc Mines, Ltd., after a particularly hard winter's experience, owing to the frequent recurrence of snowslides, has at length succeeded in re-establishing railway communication, so that the shipment of zinc ore from the Lucky Jim mine to the United States has been resumed.

Mr. M. E. Purcell, superintendent of the Consolidated Mining and Smelting Company of Canada's Centre Star-War Eagle group of mines, returned to Rossland, B.C., on March 31. After having attended the annual meeting of the Canadian Mining Institute at Ottawa on March 5-7, as representative of the Western Branch, of which he is chairman, Mr. Purcell went to Montreal, New York, and Washington, and thence back to Canada via Buffalo and Niagara Falls. After a short stay in Toronto he returned to British Columbia.

Mr. A. E. Rand, of New Westminster, B.C., has been visiting Los Angeles, where he met Mr. Thomas Kiddie, metallurgist, formerly of Vancouver, B.C. Mr. Rand is largely interested in mining properties in Nelson mining division, including a large group of claims within a few miles of the town of Nelson, and the Dundee property in Ymir camp.

Mr. Thomas Russel, for about 20 years actively connected with the management of coal mines on Vancouver island, and who last year resigned as manager of the Extension colliery of the Canadian Collieries (Dunsmuir), Limited, is now practising as a consulting coal mining engineer, with headquarters in Vancouver, B.C.

Mr. Sam Silverman, now of Spokane, Washington, who in the nineties was interested in mining properties in Kootenay district of British Columbia, and later operated a copper mne on Prince of Wales island, Alaska, recently accompanied Mr. James Cronin, manager of the Standard silver-lead mine, to that property, which is situated near Silverton, Slocan lake, B.C. The party also included two visitors from Salt Lake City, Utah.

Mr. Alex. Smith, of New Denver, Slocan lake, B.C., manager and one of the owners of the Surprise silver-lead mine, on the divide between Cody and McGuigan basin, Slocan, has been spending the latter part of the winter in Vancouver. After several years' persistent development work, the Surprise is now sufficiently opened to commence the shipment of ore to the smeltery as soon as it shall be practicable to haul heavy loads to the railway at Sandon.

Mr. O. B. Smith, Jun., general mining superintendent for the Granby Consolidated Mining, Smelting and Power Co., has returned to Vancouver, B.C., from a trip to Boston, New York and other eastern cities. With him on his journey westward was Mr. R. P. Williams, western representative of the Ingersoll-Rand Co., who had also been on an eastern trip.

Mr. Wm. Fleet Robertson, of Victoria, provincial mineralogist for British Columbia, has returned to his headquarters in the capital of the province, after having attended the meetings, in Ottawa, of the International Geological Congress Organization Committee and the Canadian Mining Institute. Before returning West he also visited New York City.

Prof. Francis A. Thomson, of Pullman, Washington, head of the Department of Mining Engineering of the State College of Washington, spent the Easter vacation at Victoria, B.C.

Mr. G. B. Webster, who a short time ago returned to New Denver, B.C., from a visit to eastern Canada, has commenced to work, under lease and option of purchase, the Neepawa silver mine, in the "dry belt," Slocan City mining division.

Mr. W. E. Zwicky, of Kaslo, B.C., general manager of the Rambler-Cariboo Mines, Ltd., in McGuigan basin, Slocan, has put men back to work in the low-level tunnel being driven to open the Bayne mine at considerablely greater depth than its old workings reached. For a time work had to be suspended on account of there being too strong a flow of water to allow of driving being continued at reasonable cost.

Mr. G. J. MacKay, a graduate of the School of Mining, Kingston, who, in 1910, was nominated by the Canadian Mining Institute for a post-graduate course provided by the Institution of Mining and Metallurgy, has just been appointed to an important position as metallurgist for the Machavie Gold Mining Co., at Potchefstroom, Transvaal. Previous to this appointment he was assistant metallurgist at the Angelo Deep.

# SPECIAL CORRESPONDENCE

## NOVA SCOTIA.

At the next annual meeting of the Nova Scotia Mining Society a proposal will be brought up to move the headquarters of the society to Sydney, and no doubt an animated discussion will take place. There is, however, a great deal to be said in favour of that, with the single exception of coal, the mineral production of appreciable output of tungsten ore, and a little barytes, but the gold mined is the lowest for many years, and iron ore seems to have disappeared altogether. Coal shows a good increase, but, practically, the entire increase comes from Cape Breton, and from the Sydney coal field at that. The two large companies of the Sydney coal field, namely, the Nova Scotia Steel and Coal Co., and the Dominion Coal Company, mined 84 per cent. of the provincial output, and contributed the not inconsiderable quantity of 40 per cent. of the entire output of Canada. Correspondingly, the major portion of the revenue of Nova Scotia, came from the coal royalties earned in the neighbourhood of Sydney. For these and many other reasons the persons who urge the removal of the Nova Scotia Mining Society's headquarters to Sydney consider that it would be a more suitable place for the consideration of mining problems than Halifax.

Sydney and the vicinity is very poorly provided with educational facilities. It is now too late to urge that the Nova Scotia Technical College would have been better placed in Sydney than in Halifax, but it is an undoubted fact, so far as the engineering branches of technical training are concerned. The mining schools and other educational opportunities afforded to those who have left the elementary schools and commenced work are doing and have done extremely good work, but it is quite impossible to furnish these schools with the elaborate equipment of philosophical apparatus that is necessary for the adequate demonstration of such phenomena as that connected with mine gases, for example. The presence of a properly fitted technical college, primarily intended for day students, would make it possible to use the same equipment for evening schools, and such an institution at Sydney would make an admirable centre for the workers of Sydney mines and Glace Bay, in addition to the students from Sydney itself. Instruction at the ordinary mining school, supplemented as it so often is by correspondence courses, and by actual work during the day, has produced the great majority of the men in charge of the technical operations of the mines and steel works of Cape Breton, but education obtained in this way requires years of hard grinding, and imposes cruel limitations on hard-working men. It is one thing to read about certain phenomena actually demonstrated before one's eyes, and it adds a variety and a zest to study that is very welcome after the steady plodding that pure reading

involves. The man who hears the ascending and descending scale of detonations caused by graded admixtures of "gas" and air, and who watches the effect of a handful of coal-dust in an explosive mixture of gas and air, has a much more vivid and permanent knowledge than if he can only learn from books, or the words of a lecturer.

Some time ago the Technical Education Commission visited Cape Breton, and the result of their labours is anxiously awaited. It is quite certain that the members of this commission did not visit a coal and steel centre in Europe of similar importance to Sydney that did not have a properly equipped technical school within reach of the workers. And if rumor is true there are towns in the Canadian West with far less natural wealth than Sydney, where the value of technical education is appreciated. The question of technical education in Nova Scotia has been put to a political use, but indeed it would be difficult to name anything in Nova Scotia that has not. The present presentation of the case has, however, not the remotest connection with party use of the question, but is a claim that a population of between 40,000 and 50,000 persons dependent on coal-mining and steel-making should have access to a technical school or college properly and adequately provided with the needful apparatus.

**Port Hood Mine.—Inverness Co.**—The report of the Inspector of Mines for Nova Scotia and the "Appraisers as to Cause of Accident, etc.," on the flooding of the Port Hood Colliery, has been laid before the Nova Scotia Legislature. The opinion of these gentlemen as to the cause of the accident is given as follows:—

"Our conclusion is that the mine is flooded by the water of the ocean, and we are more inclined to believe that it was through a fissure in the rock more nearly vertical in direction, than that the water followed the strata a long distance finally making its appearance in the mine at the point above described.

"We recommend that it is not advisable to undertake the unwatering of the Port Hood Mine for some time to come, for the reason that the connection with the sea as far as can be ascertained is not closed, and that the water having risen as high in the mine as it is likely to, the conditions against the fissure closing are in a great measure removed."

The report as issued is but preliminary, and does not contain certain data referred to, nor the evidence given before the commission. This wall no doubt be issued to the public at a later date. The report also contains a reference to the flooded mine at Mabou. Comment on this matter would be out of place until the complete report, with the evidence, is published.

## ONTARIO

**Porcupine and Swastika.—The Strike Aftermath.**—Of the first importance to the mining industry are the decisions rendered by Judge Kehoe on appeal from the convictions of Magistrate Torrance, under the Lemieux Act. It will be remembered that the Hollinger Mines induced the Crown to take action against 302 of their men for going out on strike without notice, and also to prosecute William Holowaska, Peter Cleary and Croft for inciting. Holowaska and Cleary were each fined $500 each and cost or three months in jail. Croft was fined $50 or 60 days. All the men refused to pay fines, and went to jail. As the result of the application of their counsel to the Minister of Labour and the Minister of Justice the three men were paroled and released under the ticket of leave act after they had served twenty days of their sentences. Appeals were then made and all three cases were retired before Judge Kehoe in Porcupine on March 26th. As a result he reversed Magistrate Torrance's decision in the cases of Holowaska and Croft and confirms it in the case of Cleary.

The following is Judge Kehoe's decision in full:—

Rex vs. William Holowaska.

A. G. Slaght for appellant,

T. C. Robinette, K.C., and Mr. John Godfery, for respondent.

"This is an appeal from the conviction made by Mr. Thomas Torrance, Police Magistrate, on the 21st January, 1913, under which the defendant was convicted under section 60 of the Industrial Dispute Investigation Act, 1907, and being chapter 20 of 6-7 Edward VII., for inciting to strike contrary to the provision of the Act. By this is meant, according to section 56, a strike which is unlawful by reason of an employe going on strike "on account of any dispute prior to or during a reference of such dispute to a Board of Conciliation and Investigation under the provisions of this Act." There is a lengthy clause, section 2, sub-sec. (c) which defines the meaning of the word "dispute," the effect of which is that it means "any dispute of difference between an employer and one or more of his employes" as to certain things therein generally stated, or as to any other things therein, specifically mentioned, such as wages, hours of employment, material supplied and alleged to be bad, unfit or unsuitable, established customs or usage, interpretation of agreement, and other matter.

Dumps at Savage Mine. Enough to run ten stamps at McKinley Mill for three years

"It was not proved before me, nor was it necessary to prove that there was any reference to a Board of Conciliation or that there was any request for the same.

"The evidence shows that the first sign of dispute was the strike itself, or rather the inciting by the defendant of the strikers. The strike followed this inciting. As the prosecutor stated, the strike came to him with so much surprise that it was like a thunderclap. It appears that there was no demand for increased wages, shorter hours of labour or anything of any kind until the defendant called upon the men to strike. This call was the very beginning of the dispute. There cannot be a dispute or difference unless there are two parties who dispute or differ with one another. It may be, and without doubt must have been the case here, that the strike was pre-concerted among the men, though there is no evidence that this is so. But stating it as strongly for the prosecution as possible, and allowing that the strike was the result of a previous understanding between the men, still matters did not reach a stage where there was a demand by the men for better terms and a refusal by the employer, the Hollinger Mines Company, of what the men asked. When such a demand and a refusal were not made, can it be said that there was any dispute until the strike itself created the dispute? If the answer be that there was no dispute until the strike itself then will come the necessity of answering another question. Did the men go on strike "on account of any dispute," to quote the words of section 56?

"In my opinion the defendant is not brought within the Act as an offender under sections 56 and 61 for the reason that the strike was not on account of any dispute. To hold otherwise would be to eliminate the words "on account of any dispute" from section 56. If these five words were not in the section, then it would be clear that the defendant by his inciting was guilty of an offense.

"The Act when framed might have been so framed with or without these words. One cannot assume that they were placed in the section without it being intended that they were to have a meaning and, perhaps, were intended for a purpose. Possibly it was considered that when a strike comes like a bolt out of the blue instead of like a storm of which there is premonition there is not the danger to the peace of the community that would be engendered by the antecedent mutterings.

"Another consideration is that penal statutas must receive a strict construction.

"The conviction is quashed with costs to be paid by the prosecutor to the defendant, which costs I fix at $50."

Rex vs. Croft:—

"The same decision was reached in this case as in the case of Holowaska."

Rex vs. Peter Cleary:—

"There is a difference in the circumstances of this case from those in the Holowaska case; the inciting was done after the strike had started. I confirm the conviction. The costs of the appeal, which I fix at $50, are to be paid by the defendant to the prosecutor."

**Kirkland Lake.**—There is no doubt of the growing of the Kirkland Lake section of the Swastika Camp. The Tough claims occupy the centre of the stage and the narrow but very rich ore body has now been proven to a depth of 70 feet. It is stated to be the intention of the management to sink right at once to the 200-foot level. Another carload of ore will be shipped before this is in print, after which it will be crushed in the little five stamp mill, which has already reached the property, but which has not been set up yet. Among reliable engineers there is now much optimism expressed of the future of the camp. While the ore bodies are not large they are well defined and easy to follow, thus obviating the heavy development costs of Porcupine, where the veins are much faulted and the most careful exploitation work is necessary. The Foster Tough has of course more than paid its way from the very start. The Hughes claim, which has now been taken over by the Great Northern Mines, is regarded as being second in importance in the new district. It is on the southwest shore of Kirkland Lake, and, unlike the Foster, is entirely in the porphyry. The high-grade streak is no more than eight inches wide, and, while being rich, it is not as rich as the Foster. The Crown Reserve Mining Company had an option on this property at a big figure with quick payments. On that basis they turned it down. The Great Northern obtained it on much easier terms. The vein has been traced and stripped in places for 300 feet. Recently an engineer took channel samples for two and a half feet on either side of the vein for a distance of 150 feet. and the results showed good milling ore for the entire width of five feet. A small plant will be installed and work proceed on an economical scale.

For the mining of these small, high-grade veins it has been demonstrated that the equipment needed is inexpensive and the initial outlay inconsiderable. Though they may not enjoy long life, returns from some of them will certainly be quicker than the average quartz gold mine.

So far, mining has proceeded along workmanlike lines, and little has been spent on frills. The Government is going to build a good road from Swastika to the Kirkland Lake, so that it is most unlikely that the settlement will be split up into two or three sections, as at Porcupine.

**Swastika.**—The Swastika mill is now running and paying current expenses. The slime table has not yet been installed, and not a very high recovery is being made. as so far only one sand table is being used. About twenty tons a day are being treated, the ore coming from the 100-foot level. Development is proceeding both ways on the 300-foot level, and occasional patches of ore of good grade are discovered.

A Buffalo syndicate has taken a working option on the Foley-O'Brien. The shaft has been pumped out, and it is understood that the mine will be running again shortly.

The new mill at the McIntyre mine is now running to capacity. One hundred and fifty tons are being treated daily and the management states its satisfaction with the extraction obtained.

At the McEaeneny mine an order has already been given for five more stamps.

Results have already been obtained by the diamond drilling on the Schumacher syndicate. At a vertical depth of 400 and 800 feet two gold ore bodies from which gold is visible in the cores have been cut. Up to March 28th no less than a thousand feet of drilling had been done within the month, and the contract, which called for 1,050 feet, was completed in March.

It is now announced that the shaft at the Pearl Lake will be put down to the thousand-foot level without delay. It is now seventy feet belowe the 600-foot. No official statement has as yet been made as to values.

**Cobalt, South Lorrain and Gowganda.**—The draining of both Kerr and Cobalt lakes will undoubtedly be proceeded with once the mining companies principally concerned are allowed to do so.

Last spring an amendment was inserted in the Ontario mining law giving mining companies the power to drain lakes "where required for the proper working of a mine" after the Mining Commissioner had heard the parties interested and given his permission. The section under which it was proposed to act reads: "The lake, pond, river or stream or watercourse, or any of the water, notwithstanding that the same or part othe water, notwithstanding that the same of part thereof may be on the lands of or owned by any other person or that any other person may have rights or interests in or to such water or the use thereof."

By such draining of Kerr Lake, a good many million ounces of silver could be mined on the properties of the Kerr Lake and the Crown Reserve which is now held intact and, in addition, it would give opportunity for the freer prosecuting of considerable valuable territory not now accessible. Some time before the case should have come before the Mining Commissioner action was taken in the courts to prevent any further progress.

At Cobalt Lake, which it is also proposed to drain, it is known that considerable bodies of high-grade ore could be mined if the water could be pumped out. This would affect not only the Cobalt Lake property, but in a minor degree the McKinley-Darragh and the Right of Way.

**Peace at the Beaver.**—The strike of seventy miners at the Beaver mine has been satisfactorily settled. The cause of the dispute was the dismissal of one of the men to which the miners objected. They stated they would walk out unless he was reinstated and, upon the management refusing to do this, they left work. The mine was closed down for nine days and the mill eight. During that time the management made no attempt to fill the places of the old employes, but at the end of a week issued a manifesto to the effect that unless the men returned to work by April 3rd they would be compelled to conclude that they did not want to come back and they would fill their places. A meeting of the union was held, and it was decided to return to work, and the mine and mill are now running again.

**Lawson Prospers.**—The Lawson of the La Rose Consolidated is now getting some very high-grade ore on the 88-foot level of the No. 8 vein. When struck it appeared to be but a branch of the main vein, but it has now developed into a very rich ore body, which will raise the production from the Lawson to considerably above its normal level for the first quarter of the year.

**Eight-Hour Bill.**—The eight-hour bill for underground miners has naturally aroused considerable discussion in the camp. A deputation from the Cobalt Board of Trade waited upon the Hon. W. H. Hearst, Minister of Lands, Forests and Mines, and explained some clauses in the bill which appeared to them to be ambiguous and to be likely to cause considerable trouble in the future. The Hon. W. H. Hearst promised that their recommendations should be taken into consideration when the bill was read a second time.

**Montreal River and Lorrain.**—There is promise of further activity, both in the Montreal river district and South Lorrain this year. In South Lorrain the Pittsburg-Lorrain Silver Mining Company, which is working the Currie, have their shaft down to the 300-foot level, and are running their own plant. It is understood that there is also a prospect of a company taking over the Trout Lake Mining Company, the Beaver Lake and some other good prospects, and developing them, this summer. At Gowganda the Mann has just shipped its second carload of high-grade. At Elk Lake the completion of the railroad has enabled a number of shareholders who have seen the mines they were interested in to take a look at their properties, and there have been some private cars on the sidings during the past two weeks.

## BRITISH COLUMBIA

Information concerning reported finds of placer-gold on creeks south of Teslin lake, in Atlin mining division, Northern British Columbia, has been attracting some attention, though as yet particulars are meagre. Most published accounts lack definite details as to whether or not gold has been obtained in any quantity above a few dollars' worth, but one press despatch from Skagway, Alaska, dated March 22, stated that one man had arrived in Atlin "with several thousand dollars' worth of washed gold, the first brought out from the scene of the new strike." A communication from Mr. W. Scott Simpson, Indian agent in the Stikine River district, which lies south of Atlin mining division, dated March 2 and addressed to Mr. A. M. Tyson, inspector of Indian agencies for Northern British Columbia, has been published. It is to the effect that at present there are but few of the older Indians on the reserve at Tahitan village, the majority of the men being now in the vicinity of Silver creek, a tributary of Teslin river, which joins that river about 35 miles south of Teslin lake, into which latter the river flows. Mr. Simpson reports that on February 5 a deputation of Indians waited on him and produced a letter which had been sent to them by Atlin Indians, stating that they had found new placer diggings on Silver creek. The Indians requested him to accompany them on a claim-staking expedition and to see that their record papers and lay-over permits were properly made out. Thinking it might lead to the ultimate prosperity of the Indians, he accompanied the party, which on February 7, left Telegraph creek, a settlement on Stikine river, and on March 2 returned to that place, after turned from a visit to Atlin, after having made many enquiries, has concluded that the best way will be for the Government to open a trail from O'Donnell river, in Atlin camp (on which river new placer-gold finds were made late last autumn), to the new diggings, which, he is informed, can be reached in 90 miles from Atlin. He sent in a party of men by the longer old trail, and instructed them to return by the proposed shorter route to Atlin via O'Donnell river. On receipt of their report he will, if it be favorable, recommend the Government to at once proceed to open the proposed new trail. Meanwhile, it will be well for those who shall think of going to the reported new placer diggings to await publication of authentic information from known reliable sources, for there is likely to be the customary exaggeration on the part of those interested chiefly in inducing men to spend money in travelling and outfitting, regardless of whether or not there shall be a fair prospect of the reported new diggings poving sufficiently productive to warrant the outlay necessary to reach the locality.

**Britannia Mining and Smelting Co.**—The Britannia Mining and Smelting Co., operating a copper mine on having staked claims on three creeks. The Atlin Indians produced an ounce and a half of gold they had obtained there last fall. The Atlin Indians had obtained free miners' certificates and staked claims last November on the best-looking parts of the creeks. Various Indian tribes have staked claims to an estimated number of about 300, and white men have about as many. Under existing conditions of snow and frozen ground, it is difficult to say whether or not the new diggings will prove payable to any considerable number of miners; it is probable many of the claims will prove hard to work. Three routes to the new field have been mentioned in newspaper notices. One is via Whitehorse (in Southern Yukon Territory) up the Hootalinqua river to Teslin lake, and then down the lake to its southern end, which is about 35 miles from the locality of the new find. Another is via Skagway to Carcross (Caribou Crossing) by railway, thence to Atlin and from that camp by trail east to the creeks under notice. The third is by Wrangel, in Southeastern Alaska, and Stikine river to Telegraph Creek, and thence by trail. Hon. Dr. H. E. Young, provincial secretary in the Government of British Columbia, who, late in March, re- Britannia mountain, Howe sound, within 30 miles by water of Vancouver City, does not appear to be finding any serious difficulty in continuing its development mining, concentrating, and construction operations, for about Easter time it had approximately 600 men at work, all told, and operations were in progress in all of these several departments above-mentioned. Miners' Union officials have caused to be published in provincial newspapers statements to the effect that 700 men had struck work; as a matter of fact, less than half that number went out at the call of the Union, leaving rather more than half remaining at work. When the property was visited at Easter time by the writer of these notes, it was found that mining and extraction of ore were being carried on up at the mine, although the mine crew was 30 to 40 men short of the full number for which there is work; the long aerial tramway from the mine down to the concentrating mill at Britannia Beach was beings used for the conveyance of ore, some 500 tons of which was being sent over it daily; the work of driving the long, low-level adit—now in more than 3,600 feet, and with 1,400 feet more to be driven before the 1,200-foot raise to the 1,050-foot level of the mine workings above will be commenced—was being continued with two shifts of men; three-roomed houses for the accommodation of married men were being built near the portal of the tunnel, where the new central camp is being established, with a dozen houses already erected and ground cleared for more; large new bunk and boarding houses at this camp were occupied, and power house and machine shop were being equipped with much machinery and plant; grading for the railway from the tunnel to the top of a long incline to be made for transportation between tunnel and mill was well advanced; construction of new power house at Britannia Beach was nearly completed, and the erection of the building for the Minerals Separation process plant was well forward; erection of new houses for married employes was being vigorously proceeded with; a large new store-basement, ground-floor, and three storeys, was about finished; dock, bunker and other shipping facilities were being added to; railway connections from mill to shipping docks were being improved; concentration mill was treating 500 tons of ore daily and provision was being made for an increase to 600 tons, and, generally operations were being carried on with comparatively little inconvenience, and with good prospects of shortly having full working forces in all departments, for every day a few more men were arriving as it became generally known that the Miners' Union's efforts to prevent a continuance of operations had proved quite ineffectual. The company has stated most positively it will not recognize the Union, but will do in the future, as it has done in the past, pay good workmen the best wages obtainable at similar work elsewhere on the Coast; will give them good food and accommodation, with all reasonable provision for their health, comfort and recreation, and will provide permanent employment for all its employes so long as they shall do a fair day's work for their pay and otherwise conform to the rules under which they accept employment here.

**Want Report Suppressed.**—The Nelson Board of Trade, at a meeting of about 20 of its members, not one of these being a mining engineer or metallurgist, recently appointed a committee of three "to act with the secretary in writing to the Minister of Mines calling attention to the damage being done to the mining industry of Nelson district by such statements as have recently appeared." The statements referred to were included in a published report of the Provincial Mineralogist, a man quite disinterested, of unquestioned integrity and, withal, a metallurgist of considerable operating experience. The report gave the results of that official's investigations in connection with A. Gordon French's claims to have discovered metals of the platinum group in ores and dike matter occurring within a few miles of Nelson, identical sets of samples of which had been sent to eight chemists for determination and reported on by seven as not containing even a trace of the platinum metals. No mine manager was present at the meeting, and the chairman, who most strongly denounced the Provincial Mineralogist, is an ex-grocer, now a "mining broker" and real estate agent. The committee of three consists of a lawyer, a mechanical engineer and a jeweller. Several mine managers have intimated to the Provincial Department that they entirely disapprove of the action in this connection of the Nelson Board of Trade.

**Dividends from Metal Mining Companies.**—The total amount of dividends paid by metalliferous mining companies operating in British Columbia, of which public announcement has been made, during the quarter ended March 31, is $523,734. Four companies contributed to this total, in the following proportions: British Columbia Copper Co., $88,756; Granby Consolidated M. S. and P. Co., $224,978; Hedley Gold Mining Co., $60,-000, and Standard Silver-Lead Mining Co., $150,000. The last-mentioned company, which owns and operated the Standard mine and concentarating mill, near Silverton, Slocan lake, has paid $575,000 in twelve months, having made its first dividend distribution, of $25,000, in April, 1912, and since then a monthly distribution of $50,000.

# COMPANY NOTES

## KERR LAKE DIVIDEND.

The Kerr Lake has declared a quarterly dividend of 25 cents a share, payable on June 16th.

## INTERNATIONAL COAL.

Profits of International Coal and Coke Company for 1912 were $232,198, compared with $56,073.38 in 1911, during which latter period, however, the mines were closed for nearly eight months on account of the general mining strike in Southern Alberta.

## LA ROSE PROFITS IN MARCH.

La Rose's March production of silver was 239,934 ounces to a value of $128,733, which, with sundry income of $3,253, brings that for the month up to $131,-986.

Marketing expenses, concentration and other charges amounted to $57,882, leaving the profit for March $74,-104.

The cash statement to March 31st is as follows:

| | |
|---|---|
| Cash surplus | $1,473,509 |
| Outstanding shipments and ore at mine ready for shipment | 293,302 |
| Total | $1,765,811 |

Prof. E. Dulieux, of L'Ecole Polytechnique, Montreal, leaves on May 4th to serve a month with the French army, in which he holds the rank of lieutenant.

PROVINCE OF BRITISH COLUMBIA

## GRANBY RETURNS.

During the last ten days of March the Granby smelter treated 34,525 tons of ore from the company's own properties at Phoenix, as well as 460 tons of customs ore, making a total treatment for the period of 35,005 tons. During the ten days the blister copper shipments were 717,000 lbs., giving a total for the month of March of 2,020,000 lbs.

For the first three months of the current year the smelter has treated 305,783 tons of ore from its own mines, and 3,094 tons of custom ores, or a total treatment of 308,077 tons. The blister copper shipments for the same period aggregated 5,588,245 lbs. The figures for the three months are as follows:

Granby ore treated: January, 100,881 tons; February, 96,971 tons; March, 107,931 tons.

Foreign ores treated: January, 1,268 tons; February, 886 tons; March, 107,931 tons.

Total ore treatment: January, 102,149 tons; February, 97,857 tons; March, 108,871 tons.

Copepr shipments: January, 1,828,245 lbs.; February, 1,740,000 lbs.; March, 2,020,000 lbs.

The recovery of 5,588,245 lbs. of copper from 308,077 tons of ore smelted would give the Granby practically 18 1-7 lbs. per ton for the first three months of the current year. On a 15 cent copper market the Granby should realize from copper recovery alone the sum of $837,969 from the first quarter of the year's operations. At the same rate of production for the remainder of 1913—and there is every reason to believe this will be maintained, if not increased, as the March shipments were 191,755 lbs. in excess of those of January, although the two months were of the same number of days, and February was a short month—the copper recovery for the year should be in the neighbourhood of 22,353,000 lbs., or $3,352,950.

## COBALT LAKE DIVIDEND AND BONUS.

A second dividend of 2½ per cent., with an additional half per cent. bonus attached, was declared by the Cobalt Lake Mining Company on April 1st. As was the case with the first dividend the declaration is for no specified period. It is made payable May 20th to shareholders of record May 17th. The distribution will amount to $90,000.

Those shareholders who have deposited their stock in accordance with the agreement made with the English syndicate will receive dividends on that portion of the stock which has not been taken up. The next option, which is on 15 per cent. of the stock at 66¾, expires April 15th, and the option after that on 5 per cent. of the stock at 73 expires May 15th, so by the time the dividend is payable 55 per cent. of the stock deposited will be owned abroad if the options are taken up.

## COBALT ORE SHIPMENTS FOR WEEK ENDING APRIL 12TH.

Cobalt, April 12.—In a production of 150,000 ounces for the first quarter of 1913 the Trethewey mine shows a falling off, due to the fact that during one week in February the mill was closed down on account of repairs.

During the month of March the production ran upwards of 60,000 ounces of silver, and at present all the production of the mine is coming from the mill.

The ore shipments from the Cobalt camp last week include a car of high-grade ore from the Casey Cobalt and one from the Penn. Canadian. The Nipissing, despite its two hundred tons per day of low-grade through the new mill, is still shipping a little crude ore to the smelters.

The shipments for the past week in pounds are:

| | High | Low | Pounds |
|---|---|---|---|
| Casey Cobalt | 1 | . | 40,500 |
| Cobalt Lake | 1 | . | 65,200 |
| Crown Reserve | 1 | . | 42,700 |
| Nipissing | . | 1 | 60,900 |
| Penn. Canadian | 1 | . | 64,124 |
| McKinley-Darragh | 1 | . | 75,691 |
| Silver Bar | . | 1 | 40,000 |
| | 5 | 2 | 389,115 |

Three mines shipped bullion from Cobalt this week for the London, England, market. In all they sent out 172 bars valued at $116,001.12.

| | Bars. | Ounces. | Value. |
|---|---|---|---|
| Nipissing | 87 | 105,866.30 | $62,461.12 |
| Buffalo | 57 | 57,588.70 | 34,000.00 |
| Crown Reserve | 28 | 33,700.00 | 19,540.00 |
| | 172 | 197,154.00 | $116,001.12 |

## SCOTIA'S MARCH OUTPUT.

The March output of Nova Scotia Steel & Coal Company was as follows: Coal mined, 64,000 tons; ore mined, 52,625 tons; pig iron made, 7,200 tons; steel ingots made, 7,300 tons.

## TORONTO MARKETS.

April 12th, 1913—(Quotations from Canada Metal Co., Toronto).

Spelter, 6.25 cents per pound.
Lead, 5 cents per pound.
Antimony, 10 cents per pound.
Tin, 52 cents per pound.
Copper, casting, 16 cents per pound.
Electrolytic, 16 cents per pound.
Ingot brass, 11 to 15 cents per pound.

April 12th—Pig Iron (Quotations from Drummond, McCall & Co., Toronto).

Summerlee No. 1, $26.00 (f.o.b. Toronto).
Summerlee No. 2, $25.00 (f.o.b. Toronto).
Midland No. 1, $20.50 to $21.00 (f.o.b. Toronto).
Midland No. 2, $20.50 to $21.50 (f.o.b. Toronto).

## GENERAL MARKETS.

Coal, anthracite, $5.50 to $6.75 per ton.
Coal, bituminous, $3.50 to $4.50 for 1¼-inch lump.

### Coke.

Connellsville Coke (f.o.b. ovens)—
Furnace coke, prompt, $2.25 per ton.
Foundry coke, $3.00 to $3.50 per ton.
Tin, Straits, 48.50 cents.
Copper, Prime Lake, 15.45 to 15.55 cents.
Electrolytic copper, 15.35 to 15.45 cents.
Copper wire, 16.25 to 16.50 cents.
Lead, 4.35 to 4.40 cents.
Spelter, 5.85 to 5.95 cents.
Sheet zinc (f.o.b. smelter), 8.00 cents.
Antimony, Cookson's, 9.00 cents.
Aluminium, 26.87½ to 27.12½ cents.
Nickel, 40.00 to 45.00 cents.
Platinum, ordinary, $46.00 per ounce.
Platinum, hard, $51.00 per ounce.
Bismuth, $2.00 to $2.25 per lb.
Quicksilver, $39.00 per 75-lb. flask.

We regret to learn that Mr. W. Dixon Craig, who for so many years has been a member of the technical staff of Messrs. Drummond, McCall & Co., is about to abandon the profession of metallurgy to engage in the practice of law in the Province of Alberta.

# PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assaye Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

## PUBLICATIONS

**The Geological Survey has published maps and reports dealing with a large part of Canada, with many local areas and special subjects.**

A catalogue of publications will be sent free to any applicant. A single copy of a map or report that is specially desired will be sent to a Canadian applicant free of cost and to others at a nominal price. The applicant should state definitely the Precise area concerning which information is desired, and it is often of assistance in filling an order for a map or report if he states the use for which it is required.

Most of the older reports are out of print, but they may usually be found in public libraries, libraries of the Canadian Mining Institute, etc.

### REPORTS RECENTLY ISSUED:

**CANADA**

1085. Descriptive Sketch of the Geology and Economic Minerals of Canada. Accompanied by a geological and mineral map of Canada, by G. A. Young and R. W. Brock.
1218. Summary Report of the Geological Survey for 1911.

**NEW BRUNSWICK and NOVA SCOTIA**

1113. Memoir No. 16. The Clay and Shale Deposits of Nova Scotia and portions of New Brunswick, by H. Ries and J. Keele.
1165. Memoir No. 18. Bathurst District, New Brunswick, by G. A. Young. Maps not yet published.

**QUEBEC**

1110. Memoir No. 4. Geological reconnaissance along the line of the National Transcontinental Railway in Western Quebec, by W. J. Wilson, accompanied by a map.

**ONTARIO**

1213. Memoir No. 28. The Geology of Steeprock Lake, Ontario, by Andrew C. Lawson. Notes on Fossils from Limestone of Steeprock Lake, Ontario, by Charles D. Walcott.

**NORTH WEST PROVINCES**

1204. Memoir No. 24. Preliminary Report on the Clay and Shale Deposits of the Western Provinces, by Heinrich Ries and Joseph Keele.

**BRITISH COLUMBIA**

1121. Memoir No. 13. Southern Vancouver Island, by Charles H. Clapp.
1175. Memoir No. 21. The Geology and Ore Deposits of Phoenix, Boundary District, B.C., by O. E. LeRoy.

**YUKON AND NORTH WEST TERRITORIES**

1080. Report on a part of the North West Territories drained by the Winisk and Attawapiskat Rivers, by Wm. McInnes.
1228. Memoir No. 31. Wheaton District, Yukon Territory, by D. D. Cairnes. Maps not yet published.

### MAPS RECENTLY ISSUED:

**CANADA**

1042. Mineral Map of Canada. Scale 100 miles to 1 inch.

**NOVA SCOTIA**

1133. Map 13A. Kingsport sheet, Nova Scotia, No. 84. Scale 1 mile to 1 inch.

**NEW BRUNSWICK**

1181. Map 35A. Reconnaissance Map of Parts of Albert and Westmoreland Counties, N.B. Geology and topography. Scale 1 mile 1 inch.

**QUEBEC**

1178. Map 32A. Larder Lake and Opasatika Lake, Nipissing, Abitibi and Pontiac, Ontario and Quebec. Geological. Scale 2 miles to 1 inch.
1184. May 38A. Danville Mining District, Quebec. Geology. Scale 1 mile to 1 inch.

**ONTARIO**

964. Geological map of portions of the districts of Algoma and Thunder Bay, Ontario. Scale 8 miles to 1 inch. Second edition.
1177 Map 31A. Larder Lake, Nipissing District, Ontario. Geology. Scale 1 mile to 1 inch.

**ALBERTA**

1132. Map No. 7A. Bighorn Coal Area, Alberta, by G. Malloch. Scale 2 miles to 1 inch.

**BRITISH COLUMBIA**

792. West Kootenay sheet, B.C. Geological. Scale 4 miles to 1 inch.
1237. Map 62A. Nelson and vicinity, British Columbia. Geology and topography. Scale 1 mile to 1 inch.
1247. Map 69A. Route map of part of Nass River, British Columbia. Scale 8 miles to 1 inch.
1219. Map 54A. Nanaimo Coal Area, Vancouver Island, B.C. Scale 1½ miles to 1 inch. Contour interval 100 feet.

**YUKON and NORTH WEST TERRITORIES**

1089. Map 9A. Explored Routes on parts of the Albany, Severn and Winisk Rivers. Scale 8 miles to 1 inch.

**NOTE.**—Maps published within the last two years may be had, printed on linen, for field use. A charge of ten cents is made for maps on linen.

The Geological Survey will, under certain limitations, give information and advice upon subjects relating to general and economic geology. Mineral and rock specimens, when accompanied by definite statements of localities, will be examined and their nature reported upon. Letters and samples that are of a Departmental nature, addressed to the Director, may be mailed O.H.M.S. free of postage.

***Communications should be addressed to THE DIRECTOR, GEOLOGICAL SURVEY, OTTAWA.***

PUBLISHED JANUARY, 1913 — PUBLISHED JANUARY, 1913

# MINING ENGINEERS' EXAMINATION AND REPORT BOOK

By CHARLES JANIN (*Consulting Mining Engineer*)

In Two Parts Part I, 94 Pages, $5\frac{1}{2}$ x $7\frac{1}{2}$ in. Leather; Part II, 57 Pages, $7\frac{1}{2}$ x 5 in. Boards — $2.50 Postpaid

PART I is a handbook covering examination of and reporting upon mines and mining property. Part II is a skeleton report, serving three purposes: *First*, an outline of a model report; *Second*, a field note book; or *Third*, a blank form on which the final report may be submitted.

The first pages of Part I are devoted to an enumeration of the points which a complete report should cover. These pages also constitute detailed instructions for filling out the blanks in Part II. The sub-headings are: Names of Claims, Location, Titles, History, Topography, Geology, Mining Facilities, Equipment, Development, Methods of Working, Production, Methods of Ore Treatment, Sampling, Ore Reserves, Operating Costs, Mine Valuation.

The examination of placers is fully discussed and an outline of a placer report is given. Methods and cost of Sampling with Keystone and Empire Hand Drills are included.

The following headings give the contents in brief of the remaining pages, each subject being treated in a short, concise, but accurate article: Examination of Title, Blank Forms, Classification of Igneous Rocks, Study of Ore Deposits, Representative Costs (including much actual cost data), Weights and Measures, Conversion Tables and Factors, Amount of Material Required for Buildings, Water Power (including the flow of water in flumes, ditches and pipes; horse power of water, etc.). Power Plants, Transmission Lines, Relative Values of Wood, Coal and Oil for Fuel, Company Reports, Flow Sheets, etc. Blank pages for individual notes are included.

Part II may be used to serve either of the three purposes noted above. It is printed upon a good bond paper which takes ink freely. On the pages intended for maps a background of cross section paper is printed in gray ink, making an ideal sketching medium. Part II fits snugly in a pocket at the back of Part I and the complete work will go easily into the ordinary coat pocket. Part II is sold separately at 50 cents each.

# Amatite

## ROOFING

### Mineral Surfaced—Needs No Painting

Everything about Amatite appeals to the man with common sense. He can see its superiority at once—the real mineral surface *which never needs painting* the two layers of Pitch, which is the greatest waterproofing material known; the two layers of heavy Tarred Felt—all these contribute to the popularity of Amatite.

We can make Amatite better and cheaper than anyone else on account of our greater facilities, and consequently we sell it at a surprisingly low figure.

Simply the fact that it needs no painting is enough to make a man sit up and take notice—especially the man who has spent time and money in painting and repainting smooth surfaced roofings.

Write to-day for further information.

CONTENTS.

## COMMISSIONER PRICE'S REPORT

The results of the informal enquiry conducted by Mr. Samuel Price, Mine Commissioner for Ontario, have been embodied in a report to the Honourable W. H. Hearst, Minister of Lands, Forests, and Mines. Taken in its entirety, despite the fact that there is much internal evidence of Mr. Price's unfamiliarity with the practical aspects of mining, the report can be described as painstaking and, in many respects, accurate. We are convinced, however, that those in authority intended from the first to pass the act limiting the time of underground labour to eight hours per day.

Mr. Price states at the outset that his investigation for the most part took the form of an informal enquiry, although every opportunity was given to employers, managers, and workmen to voice their sentiments individually and collectively. In his endeavour "to ascertain and understand the nature of underground employment in the mines and the conditions under which men work," the Commissioner communicated with mine managers throughout the Province, held public meetings in various mining centres, caused secret ballots to be taken amongst the men, and corresponded extensively with officials in other countries. He claims, in effect, to have given equal opportunities to both mine owners and employees. Whether he could or could not do this is a question that we shall touch upon very briefly. As there are about 4,000 men employed underground in the Province, and as each presumably has a vote, it is frankly to be doubted whether a Government official could handle the situation without at least a tincture of unconscious bias. The Government has far too much at stake to take unnecessary chances. Far be it from us to accuse the Ontario Government of deliberate unfairness; yet we cannot but percieve the unwisdom of the method chosen.

In discussing the attitude of the men, the Commissioner said that nearly all are in favour of an eight-hour day. Out of a total ballot of 344, only 12 voted adversely to the proposed limitation of hours. "In nearly all the mines where the ballot was taken, I am satisfied," says Mr. Price, "that the men as a rule are well treated *and not at all dissatisfied in general* with the way they are used by their employers." The italics are our own. The clause italicized is most significant. Could a similar statement be made concerning any other industrial occupation? And why, in the name of reason, should the mining industry be selected by a paternal Government when there are numberless real abuses crying for attention in other industries?

The only apparent explanation can be found in the 4,000 reasons referred to above.

The principal arguments adduced by the men in favour of the change are: That underground work is unnatural and trying; that the hydraulic air used in Cobalt is "not as good as the air of the ordinary compressor;" and that eight hours of work is the longest continuous period in which efficiency can be maintained. To these claims it may be answered that underground work is no more "unnatural" than work in any building, or on a ship, or on a locomotive. And, as a matter of fact, it is infinitely more wholesome and much more remunerative than the majority of vocations. As to the implication that the hydraulically compressed air used in many Cobalt mines is detrimental to the health, we may frankly say that we do not believe it. That eight hours of efficient work is all the ordinary man is capable of, may or may not be true. This depends much upon the men, and to some extent upon the manager. It is demonstrable, however, that under present conditions it is practically impossible to be sure of more than six, or at most, seven hours of actual labour from the men. Supervision of underground labour is costly and difficult. This is a point that has been overlooked by Mr. Price.

The mine managers, according to Mr. Price, were practically unanimous in opposing the eight-hour day. Less than half a dozen managers were wholly in favour of it. Others signified their approval of the change if the hours were to be calculated "face to face." It was specifically pointed out that an eight-hour day would induce a reduction of wages and much dissatisfaction among the men. That, further, it would decrease outputs and lessen profits, and that many low grade deposits would be removed from the category of commercial possibilities. The contention that underground labour is injurious to the health was flatly contradicted by the managers. And in this last item they had, beyond doubt, by far the best of the argument. But, as noted before in these columns, the statement that Cobalt has reason to fear competition with Mexican silver producers is vain and foolish.

In reviewing the whole matter, Mr. Price expresses the belief that no one can predict what the effect of the enactment of an eight-hour law will be. A slight increase in the cost of production will, he admits, be probable. It will not, however, have any serious effect. Amongst the specific ills to be feared is the growth of miners' phthisis, a disease not at present known in Ontario mines. Parenthetically, we would like to ask Mr. Price how an eight-hour day can prevent the development of this malady? The steps to be taken for its prevention are well known. They consist chiefly in the application of water sprays for allaying drill dust. The mechanical devices necessary can be adopted whenever occasion arises.

Mr. Price admits that there is not an abnormal percentage of sickness amongst the miners. But, in discussing the relative healthfulness of underground work, he entirely omits consideration of the fact that the miner is not exposed during working hours to inclement weather and to variations of temperature. In fact, year in and year out the miner works in an atmosphere the temperature of which is practically standardized. This applies particularly to Ontario mines, none of which are deep enough to develop an appreciable increment of temperature.

Space forbids us to touch upon many of the points brought forward in the report. Suffice it to say that there is every evidence of painstaking care. It is observable, however, that Mr. Price, in his summation of conclusions, has been at some pains to labour those points that are in favour of the proposed change. This may be illustrated by one paragraph: "I think there is something, too, in the contention that the shorter day would tend to greater skill and efficiency of the men, and that by improving conditions it would encourage a more permanent class of residents in the mining camps and lessen the very large remittances of wages now sent out of the country by those having no established home here."

From the tone of this paragraph we are led to conclude that Mr. Price forgot the important fact that his function was primarily judicial. He seems to be not the judge but the advocate.

## METAL MINE ACCIDENTS IN THE UNITED STATES.

Comparative statistics show that fatal accidents in the metal mines of the United States are deplorably numerous. During the calendar year 1911, for instance, of the 165,979 men employed in the metal mines of the States, 695 were killed, a rate of 4.19 per 1,000 men employed. In the Transvaal, where labour is less intelligent, the rate is higher, 4.29 per 1,000. But in Great Britain, Germany, France, Spain, Australia, Japan and other countries it is markedly lower. The lowest rates obtain in New Zealand and Australia, where records show less than one man killed per 1,000 men employed.

As might be expected from the nature of the work, the great preponderance of metal mine fatalities mean the death of one man at a time, rarely more than ten or twelve. In coal mines the majority of reported accidents are catastrophes involving the deaths of scores.

The copper mines of the United States employ about 30,000 men underground. In these mines the death rate from accidents is 5.33 per 1,000 men employed. In the iron mines the rate is 4.29; in the zinc and lead mines, 3.43; in gold and other metal mines, 3.95; while in other mineral mines the rate is 1.73.

Striking a general average for all mines other than coal mines, falls of rock from roof or wall accounted during 1911, for 27.48% of all underground fatalities; explosions for 8.92%; haulage accidents for 2.88%;

mine fires for 5.32%; falling down shaft, 8.20%, and objects falling down shaft, 4.15%. These are the most serious causes. In addition to State inspection and Federal control of explosives, the most important work being done in the direction of prevention is the publicity being given in the form of detailed information collected and distributed by the U .S. Bureau of Mines.

## TEMISKAMING ANNUAL REPORT

Few mining companies have been such storm centres as has been the Temiskaming Mining Company, Limited. Its pugnacious president, Mr. Burr E. Cartwright, however much he has been criticized, and however much he may have merited that criticism, is certainly a generalissimo of no mean ability.

The authorized, and issued capital of the company is $2,500,000. Including $300,000 distributed during the calendar year 1912, the mine has yielded altogether $1,309,155.56 to its shareholders. Last year's net earnings amounted to $413,615.87, of which sum $300,000 went to dividend payments and the remainder was carried forward as balance, making the total surplus $590,591.71. The production of silver for the year was 1,242,243 ounces. an increase of only 28,489 ounces over the previous year. One noteworthy item is the production of 16,037 pounds of copper, the first commercial shipment of that metal from Cobalt.

A substantial lessening of operating costs is reported by the general manager, Mr. Norman R. Fisher. The cost of breaking and raising 31,449 tons of ore was $166,256, or $5.28 per ton, whereas the average cost during the year 1911 was $6.85.

Milling costs also were lowered. In 1911, the cost per ton of ore treated was $1.99; while during 1912 the average cost was reduced to $1.72. Mill recovery was improved, being brought up from 80% to 82.1%. In brief, the technical history of the year appears to be eminently satisfactory save for the fact that no statements, beyond vague references to promising new developments, have been made as to ore reserves. The mine maps indicate in a general way that the mine's future must depend very largely upon the results of prospecting. The ore available may not be sufficient to maintain production for more than half a year. On the other hand, the history of the Temiskaming encourages the belief that prospecting will be handsomely rewarded. And it is doubtful whether the development of regular ore reserves is commercially practicable.

The North Dome mine, the Temiskaming Company's property in South Porcupine, is dismissed in one brief paragraph. Hence there is no basis furnished for discussion.

Mr. Fisher deserves much credit for the workmanlike way in which the report has been prepared. His tabulation of costs is admirable. Both the engineer and the printer have taken pride in turning out a good job.

## CONCERNING THE BARTLETT.

We have before us one of the most extraordinarily inaccurate mining reports that it has ever been our painful duty to peruse. The document purports to deal with the Bartlett mine, Gowganda, Ont., and to it is affixed, in typewriting, the name "H. Brian Pearson." From beginning to end it is a strange medley of inaccuracy and misstatement.

The author, in his opening paragraph, informs us that the T. & N. O. Railway will, in the near future, be completed to within one and a half miles of the mine. This, we fancy, will be news to the Government and to Chairman Englehart. This, however, is merely a "marker." One statement reaches the ultimate of futility. "It is noticeable," runs the report, "that in each instance when either nickel or cobalt bloom obtains at the surface, a shoot of rich silver ore has been found by sinking." Nothing more completely misleading could be put in words. Only an incompetent or a knave could write such nonsense.

It is needless to quote further. Mr. Pearson's report is a masterpiece of silliness and distortion. But, futile as the report may seem to those who know the region, it is unfortunately true that the great mass of outsiders can readily be deceived. In other words, reports like this are mischievous and dangerous. They discredit the district and the profession.

If Mr. H. Brian Pearson be actually responsible for this "pipe dream," he should certainly be visited with condign punishment should be venture to call at Gowganda in the future.

## EDITORIAL NOTES

That poor dear Mrs. Ella Rawles Reader has at last come to grief. As promoter of the Calumet Metals Co. she won the confidence of not a few of our wealthy men. She sowed the wind, and now the inveigled shareholders are reaping the whirlwind.

Mr. W. A. Caldecott has calculated and tabulated the weight of tube mill pebble loads for 22-foot mills of diameters ranging from 54 inches to 63 inches. The loads are graduated by inches from 12 inches above the axis to 12 inches below, and the weight of a cubic foot of pebbles is taken as 105 lbs. For a 54-inch mill the maximum load is thus 14.21 tons of pebbles, the minimum 4.16 tons; while for a 63-inch mill the corresponding figures are 18.42 tons and 6.58 tons.

A recent writer comes to the conclusion that, to avoid errors in sampling and assaying ores that carry coarse gold, certain precautions are effective. When, for instance, relatively few grains of unusually coarse gold are present, the sample should not be put through a finer mesh than 30 or 40-inch, and fusions should be made in triplicate, abnormally high results being rejected.

---

The Mines Branch of the Dominion Department of Mines has issued a bulletin giving a list of all Canadian coal mines. The tabulated information includes the names of the operator, the head office address, the colliery designation, the location of the colliery, the mine office address, and the name of the manager. This will be of great service to many engineers, machinery men and investors. Incidentally, we note that our old friend, "Dr." Hugo von Hagen is named as manager of three coal companies in New Brunswick. How this same von Hagen has eluded so long the clutch of the law is a mystery to us.

---

The amount of time and labour being expended upon the volumes under preparation for the International Geological Congress is astonishing. The Coal Atlas itself includes more than 70 maps, many of which are printed in four colours. The text of the three volumes, which are now in press, is three-quarters English and one-quarter French and German. The coal resources of every country in the world are dealt with. Proof reading alone is a task of considerable magnitude.

# CORRESPONDENCE

## CORE DRILLS

Toronto, March 25, 1913.

Editor Canadian Mining Journal, Toronto, Ont.

Sir,—In pursuance of your request of this date, I beg to state that the illustrated lecture given by me before the Canadian Mining Institute on March 7th consisted of an exhaustive series of notes taken on shot drill operations in various parts of this continent and Europe. It had to do particularly with core drill work where cores are being recovered from 3 inches in diameter to 29-inches in diameter. 70 lantern slide pictures accompanied the article along with many data as to costs, speed of drilling, cost of drilling outfits, etc., under different conditions. An interesting picture was shown on "Core Drilling in China" before the Christian era. In connection with this picture it may be noted that many of the drilling terms used by the Chinese are still in use to-day.

I find it generally true that mining engineers, as a whole, know but little of core drill work where cores have to be recovered of over 3-inches in diameter. Notwithstanding this, there is a large amount of core drill work going on where cores are being recovered 16½ and even 29 inches in diameter. Pictures were shown of this work.

P. H. MOORE,
Mining Engineer for the Canada Foundry Co.

---

# THE GOLD OF THE KLONDIKE

By J. B. Tyrrell, F.G.S.*

The Klondike gold-bearing district, in which placer deposits were discovered in the summer of 1896, is situated near the extreme north western part of the Dominion of Canada, between north latitudes 63° and 64°, and about fifty miles east of longitude 141° west, which forms the boundary between Canada and the United States territory of Alaska. Its area is not clearly defined, but for the purpose of this paper it may be considered as being about eight hundred square miles, with a width in a north and south direction of 28 miles and a length in an east and west direction of 36 miles.

In general character, the Klondike may be considered as being a small and nearly isolated mountainous region lying to the east of the great valley of the Yukon river, to the south of the smaller valley of the Klondike river, and to the west of the still greater valley which runs to the south-west of the Rocky Mountains. On its southern side it is more or less closely connected with irregular mountainous ridges to the south of it, but the valley of the Indian river separates it more or less completely from them, except in the extreme south-eastern portion.

The lowest point in all this region is the bed of the Yukon river, where the Klondike river joins it at the City of Dawson, with an approximate elevation of 1,200 feet above the sea.

The highest point is situated about the middle of the area, twenty-nine miles south-east of Dawson, and is known as the "Dome." This is a hill or mountain with an approximate elevation of 4,250 feet above the sea, or 3,050 feet above the Yukon river at Dawson.

*Abstract of paper read before the Royal Society of Canada.

From the Dome the country declines gently in all directions towards the valleys above enumerated, the drainage being carried off by short streams which radiate west, north, east and south, and flow into these larger streams.

The smaller streams are fairly mature in character. Many of them beginning in cirque-like depressions in the vicinity of the Dome, continue outwards with gradually decreasing grades without falls or other sudden interruptions, until they reach their mouths, while the smaller tributaries which join them on both sides flow quietly into them without any sudden changes of grade or without any waterfalls tumbling down from hanging valleys.

The area is completely isolated from any other drainage. No streams cross the district from any mountains or high lands outside of it, and there is no evidence that any streams have ever so crossed the district.

As, therefore, no glaciers have ever reached the country from any of the country to the north, or from the surrounding or adjoining mountains, and as no streams have crossed it, the problems of denudation and transportation which it presents are entirely confined within its own boundaries.

All the loose material which is found on its hills and ridges is derived from the immediate vicinity, and all the sand, gravel, or other detritus which is found in its valleys, was derived from the sides or bottoms of those valleys themselves, and none of it was brought from a distance.

**Geology.**—The rocks which underlie most of the gold-bearing district consist of altered quartz-porphyries, and porphyrites, probably of pre-Cambrian age, which have been squeezed and altered into chloritic and sericitic schists. In most places these are now standing at high angles and are striking in various directions.

Included in these schists, and usually running with their strike, are numerous veins and stringers of light coloured quartz. In some of these veins free gold has been detected, and it would appear probable that most of the gold in the district has been associated with, or has been derived from, these quartz veins.

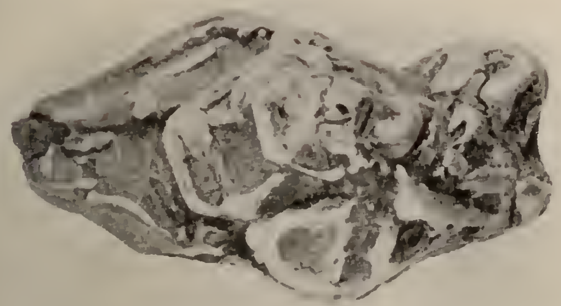

Fig. 1

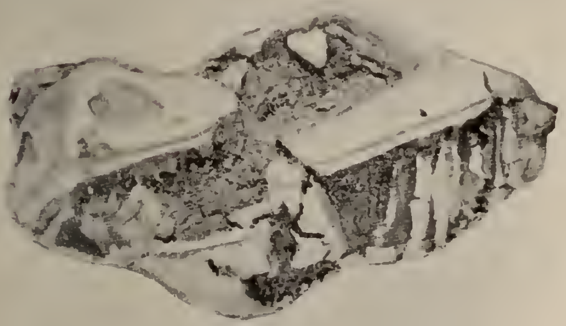

Fig. 2

Fig. 3

Fig. 4

**Figs. 1 and 2—Spinel Twin with hollow faces.**
**Figs. 3 and 4—Cube with hollow faces, &c.**
**Gold Crystals.—Magnified $2\frac{1}{2}$ diam.**

Both to the north and south of these fissile schistose the rocks are highly altered gneisses or hard quartz-mica schists, containing some bands of limestone. These gneisses, etc., also carry irregular quartz veins, and these veins doubtless also contain a little gold, but they would not appear to contain as much gold as the veins in the chloritic and sericitic schists previously mentioned.

Intrusive masess of igneous rocks, such as granite, peridotite, diabase, andesite, etc., occur here and there around the border of the chlorite scists, but as far as is at present known, there is no definite connection between any of these intrusives and the occurrence of gold-bearing veins.

Overlying all these rocks, except the andesites and their associates, Cretaceous or early Tertiary sandstones—and conglomerates occur to the north and south of the chlorite schists. In some cases they would appear to have been somewhat folded and contorted, though not to the same extent as the older rocks.

It has been claimed, apparently on good evidence, that some of these conglomerates contain gold, and they may thus be ranked as ancient placer deposits, but gold has never been found in them in paying quantities, and consequently they have not been studied as fully as the later gravels shortly to be described.

In all these rocks, but especially in the chloritic and sericitic schists, which have been called by Mr. McConnell, of the Geological Survey of Canada, the "Klondike Series," gold is found in greater or less abundance in the quartz veins which traverse them. It has also been found in the schist in minute quantities apparently not associated with the quartz at all.

These facts should be carefully borne in mind for all the gold in the detrital and placer deposits in the Klondike has been derived directly from these altered rocks occurring in the immediate vicinity of the alluvial deposits.

The gold of the Klondike occurs originally or primarily in quartz veins in the chlorite and serecite schist chiefly of the Klondike Series, as defined by Mr. R. G McConnell.

These quartz veins are usually lenticular in shape and rarely continue for more than a few feet in horizontal length. As a rule very little gold can be seen in them. As a result of a number of assays I found that while they usually showed traces of the metal, they rarely contained more than $1 to the ton. In some cases, however, notably in some quartz veins near the heads of Gay and Victoria gulches, two tributaries of Eldorado and Bonanza creeks, these veins were seen to contain coarse nuggety gold associated with pyrite. Some of it was distinctly crystaline in character, and among the crystals were a number of small triangular plates representing "spinel twins," the twinning being parallel to the octahedral face of the crystal. I had found some of these crystals in gold dust brought from Victoria gulch in the early days of mining in the Klondike, and afterwards, while examining the quartz veins at the head of the gulch, in company with Professor Henry A. Miers, F.R.S., we found a few more crystals of a similar character. Some of the crystals found on Claim No. 7, Victoria gulch, are represented on Plate 1.

In addition to the gold found in the quartz veins it is possible that some is associated with the schist itself. But none of the quartz veins so far discovered have proven rich enough to be worked at a profit, and the gold production of the Klondike has been derived exclusively from its placer deposits.

**Placers.**—Placer deposits may be defined as "Detrital deposits of heavy metals or minerals mechanically concentrated by natural agencies."

The Yukon Placer Mining Law gives the following definition: "Placer ground means any natural stratum or bed of earth, soil or gravel, containing gold or other valuable mineral or stones, derived from the disintegration of older deposits, and transported to, and concentrated in, their present position by the mechanical agency of water, but does not include mineral in place, or as defined in Part III, or the disintegrated portion of a vein, lode or rock, lying above or about such vein, lode or rock and clearly derived therefrom." This is entirely too narrow for a general definition of placers, because, while those in the Yukon have been chiefly formed and concentrated through the agency of water, some few are composed of residual or slidden material, while in other countries instances have been recorded of moraines formed in front of a glacier being profitably worked as placer ground. If amended by the addition of the words "or other natural forces" after "agency of water" the definition would be improved.

Generally speaking, however, the placers of the Yukon are gravels which have been formed by the wearing down and redeposition of the rocks of the immediate adjoining country.

Of the processes which enter into the formation of placer deposits, the following are the most important: First, rock decomposition and disintegration, or weathering; second, transportation; third, concentration, and fourth, deposition.

**Transportation.**—As seen above this whole country once formed a moderately even plain at what is now a height of about 3,500 feet above the level of the sea. Since that time it has been reduced to its present configuration. The rocks were softened by weathering and were then transported by the agency of water down the slopes, and finally for the most part into the ocean. The weathering kept well in advance of transportation, so that the hills are still covered with softened rock.

The primary force which causes this downward movement of loosened material is gravity, but the presence of water helps to loosen and separate the particles of the rock from each other, and to allow the force of gravity to be transformed into motion. This influence, of course, differs on different portions of the rock, varying according to the relative weights or specific gravities of the various substances. For instance, the force of gravity exerts a far greater influence on gold, which has a specific gravity of 19, than it does on quartz, which has a specific gravity of only 2.6.

If water is included in the loosened or weathered rock, it causes it to move gently and slowly downwards. This movement is known as "creep," and almost all slopes are affected by it. A typical instance came under my observation on one of the hills adjoining Bonanza creek. A narrow dyke of dark basic rock cut vertically through the light green chloritic schists which formed the country rock of the district. When within ten or fifteen feet of the top, it turned sharply sideways towards the face of the hill and ran horizontally until it reached the surface, being quite clearly distinguishable from the lighter coloured rock all the way. It had been originally vertical throughout; but the creep of the upper softer portion of the schists which enclosed it had turned it over so that its upper portion assumed a horizontal attitude.

This creep has a considerable influence on the formation of placer deposits, as it tends to constantly move the loosened soil and earth down from the hills into the bottoms of the valleys.

But the principal agent in the transportation of the loosened rock, and also in its concentration, is water flowing on the surface, either in minute rivulets or in larger streams.

After a heavy fall of rain little rills are formed all over the ground, and these flow downwards, carrying a load of mud with them, and gradually join together into larger streams, and finally into brooks and rivers. As they become larger with a constant slope they increase in velocity and consequently have greater carrying power.

*The following table gives the carrying power of a stream as exerted on quartz or rock of similar weight:

| Velocity of Current. | Size of material moved. |
|---|---|
| 3 in. per sec.=1/6 mile an hr. | Fine clay and silt. |
| 6 in. per sec.=1/3 mile an hr. | Fine sand. |
| 1 ft. per sec.=2/3 mile an hr. | Pebbles ½ in. diam. |
| 2 ft. per sec.=1.3 mile an hr. | Pebbles 1 in. diam. |
| 2.82 ft. per sec.=1.9 mile an hr. | Pebbles 2 in. diam. |
| 3.46 ft. per sec.=2.3 mile an hr. | Pebbles 3 in. diam. |
| 4 ft. per sec.=2.7 mile an hr. | Pebbles 4 in. diam. |
| 4.47 ft. per sec.=3 mile an hr. | Pebbles 5 in. diam. |
| 4.90 ft. per sec.=3.3 mile an hr. | Pebbles 6 in. diam. |
| 5.29 ft. per sec.=3.6 mile an hr. | Pebbles 7 in. diam. |
| 5.65 ft. per sec.=3.9 mile an hr. | Pebbles 8 in. diam. |
| 6 ft. per sec.=4 mile an hr. | Pebbles 9 in. diam. |

With rocks of equal specific gravity the carrying power of a stream varies according to the square of the diameter of the pebbles; or the volume of the pebbles which can be carried by a stream increases in the sixth power of its velocity; that is if the velocity is doubled, the diameter of a pebble which can be carried is increased four times, and the volume sixty-four times. Conversely when the current is reduced one half, the volume of a pebble (weight being equal) is reduced sixty-four times.

Thus a very slight increase in velocity greatly increases the carrying power of a stream. For instance, a stream flowing at one mile an hour has power to transport particles of a certain size, and if that stream increases in velocity to a mile and an eighth an hour, it becomes capable of carrying particles of double the volume, while if the velocity is decreased from a mile and an eighth to one mile an hour its transporting power is cut in two.

In this connection it must be borne in mind that the effective weights of different substances are not the same in water as in air. For instance, quartz which has a specific gravity of 2.6 has a specific weight in water of only 1.6, while gold which has a specific gravity of 19 has a specific weight in water of 18. Gold is therefore 7.3 times as heavy as quartz in air, while it is 11.25 times as heavy as quartz if weighed in water. It is therefore the specific weight in water of different substances which must be considered in connection with their transportation by water, rather than their relative weights in air. If the specific gravity is constant, the diameter of the pebbles which a stream can carry will vary as the square of the velocity, and if the velocity of the stream remains constant, the size of the pebbles will vary according to the specific weight of the substance composing them weighed in water. Thus, if one pebble is of quartz and another is of gold, which is 11.25 times as heavy as quartz weighed in water, the volume of a pebble of quartz which can be carried by the current will be $11.25^2$ or 126 times as great as that of a pebble of gold, and, assuming both pebbles to be cubes the diameter of the pebble of quartz will be approximately five times the diameter of the pebble of gold.

*Rivers of North America. By I. C. Russell, New York, 1909, pp. 18-19

With pebbles of quartz and gold of equal size it will take a current of $\sqrt{5}$ or 2.24 times the velocity to move the gold which it will take to move the quartz.

Again, if pebbles of quartz and gold of equal size are dropped into water the latter will sink to the bottom with more than three times the velocity of the former.

Now the quantity of material, or load, which can be collected by running water from the ground when it is covered with vegetation is relatively small, but when vegetation is absent and weathered rock is exposed to the direct influence of the rain and running water the load will often be very large, and consequently streams which carry away the wash from bare but weathered surfaces are often loaded to their utmost capacity.

In addition to the work done by water in carrying away weathered and softened rock, the streams themselves cut down their channels into the hard unweathered rock.

Where the water in the streams is clear and carries but little sediment this cutting action is very slow, or almost nil, but where it carries any considerable amount of sediment this sediment is pushed along on the bottom over the rock, and wears it down like a file, so that the bottoms of the streams, which are in this way deepening their channels, rarely, if ever, give evidence of the presence of a weathered layer of rock.

In the Klondike district it is certain that the valleys, both during the Second and Third Cycles of Erosion, were cut down by this process of downward erosion as narrow V-shaped gorges through unweathered rock to base level.

By the processes of erosion and transportation, the old Dome Peneplain has had deep and wide valleys cut in it, and most of the material derived from the cutting out of these valleys has been carried away beyond the limit of the district, either to the ocean or to some lower-lying land.

The lowest point in the Klondike area, which we are now considering, may be taken as the bed of the Yukon river at the mouth of the Klondike river, opposite the city of Dawson. In 1898 this was calculated by the author to be at a level of 1,200 feet above the sea, the calculation being then based on the assumption that the Yukon river from Lake Bennett to its mouth flowed in a parabolic curve. Since that time no exact measurements of the height of Dawson have been made, but a number of approximate levellings would indicate that the height so calculated in 1898 is not far from correct. The highest point in the area is the Dome, with an elevation of 4,250 feet above the sea.

Some years ago a contour map on the scale of two miles to the inch, with contour intervals every hundred feet, was prepared by Mr. R. G. McConnell and his associates of the Geological Survey of Canada. Some corrections were made to this map by the writer and then the area of each contour line was computed. Summing these areas together it was found that the district had a mean elevation of 2,600 feet above the sea. Assuming that the Dome Peneplain had a mean elevation of 3,500 feet above the sea, which is the elevation of those remnants of it which can be clearly distinguished, the country has been reduced under the influence of atmospheric and water erosion from 3,500 to 2,600 feet above the sea. This computation may be not strictly correct, for the Dome Peneplain may have sloped off towards the surrounding valleys, so that portions of it may have been lower than its remnants which are now recognizable, but on the other hand parts of it may have been higher than those parts which remain, and therefore it is probable that an elevation of 3,500 feet is not far from correct.

Taking a total area of 800 miles for the entire Klondike district and assuming that we are correct in our calculation that the country has been reduced 900 feet on an average, it would appear that 136 cubic miles, or 1,600 billion tons, of rock have been removed from this area since the downward erosion of the Dome Peneplain was inaugurated.

The work of removing this enormous quantity of rock must have taken a very long time, for it is not likely that rock weathers as quickly in that far northern country as it does farther south, and streams which are frozen to the bottom for half the year cannot cut down their valleys as quickly as those which have the whole year to work in. Besides that, the ground in the north has a tendency to be covered by a thick growth of sphagnum moss and other low vegetable organisms which prevent the water from wearing the surface away In the valley of the Mississippi it has been found that the country is being worn down at an average rate of about one foot in 4,000 years. If this rate is applied to the Klondike district it would mean that it has taken 3,600,000 years to reduce the Dome Peneplain down to the present configuration of the country. However, I am satisfied that the Yukon river does not carry away as much sediment as the Mississippi, and especially is this so if the glacial mud, which is brought down by the White river and other similar streams from the mountains, is eliminated from the computation. If the Yukon and its tributaries have eroded and reduced their valleys in past times at the same rate that they are eroding to-day, it is probable that a rate of one foot in 6,000 years, or even more, should be applied, in which case the time needed for the erosion of the Klondike district to its present shape would be 5,400,000 years or more.

**Concentration and Deposition.**—I have shown that the Klondike area was gradually worn down as an individual unit from the Dome Peneplain to its present shape in two successive periods, which have been here called respectively the "White Channel Period" or "Second Cycle of Erosion" and the "Recent Period" or "Third Cycle of Erosion." Both these periods may have been made up of two or more sub-periods, though that question has not been discussed here. Of the two main periods, the former, or White Channel Period, was very much the longer, and the greater portion of the erosion was performed during it.

While the erosion was in progress the eroded material was being carried down into the valleys and thence outwards to or towards the sea.

At first the streams were actively deepening or wearing down the bottoms of the valleys. Therefore these valleys were in the form of V-shaped gulches, from which all the finer and lighter material was being carried away, while the heavier particles, such as gold, magnetite, etc., were being scattered along the bottoms of these narrow valleys.

The particles of gold contained in the gravel or sand would be carried along by the water of the streams, over any smooth rock, until they would settle into crevices in the rock itself or into spaces between or among large loose rock masses, from which places they could not be dislodged except by upward currents. Such currents would first lift pebbles of quartz or similar rock less than five times the diameter of nuggets or particles of gold, before they would lift the particles of gold, even if the quartz and gold were equally accessible. But as a rule they are not equally accessible, for the lighter rocks being larger would stand higher than the particles of gold, and the spaces between them would hold and protect the smaller masses of the heavier metal from the current.

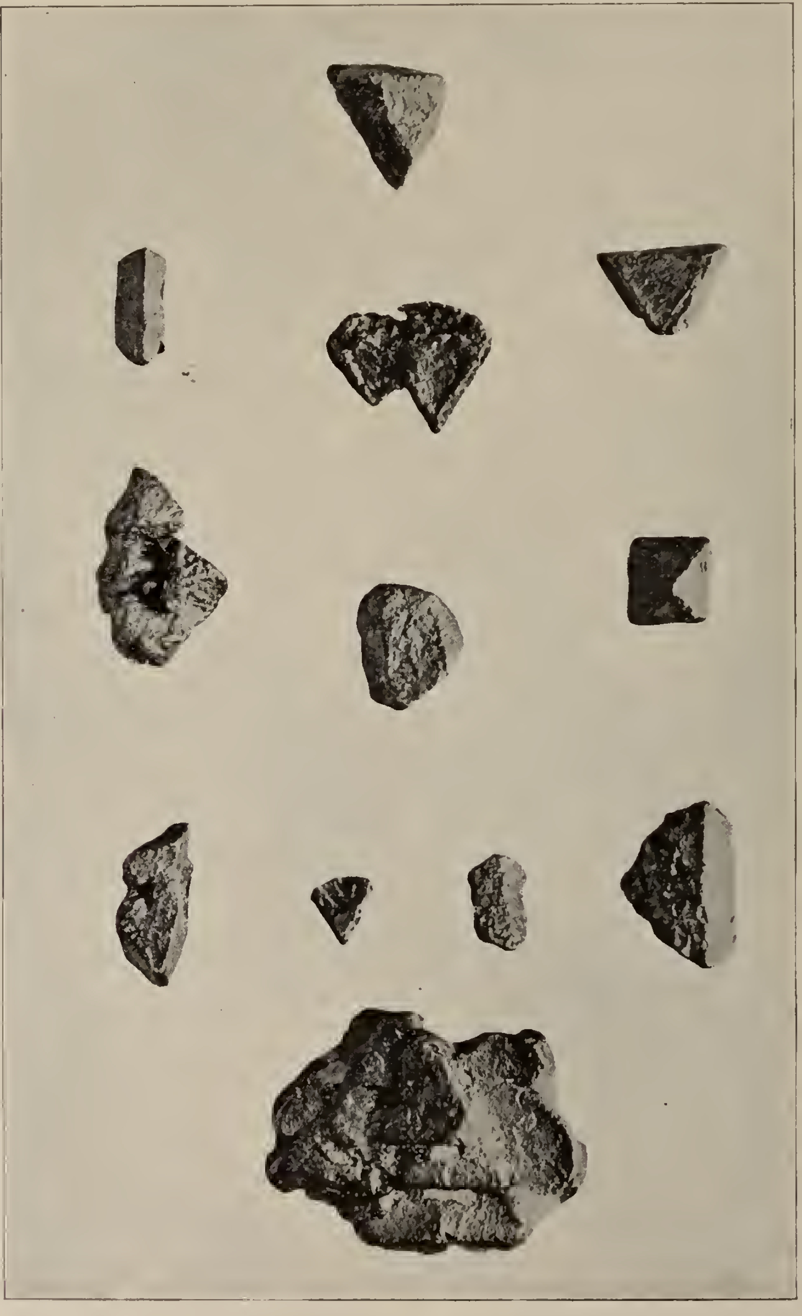
Thus the removal of gold by currents, after it has once been lodged, becomes exceedingly difficult as long as the crevices or spaces in which it is lodged persist.

While a stream keeps cutting its channel downwards new crevices or lodgment places are being constantly developed in the rock beneath the old ones which are being cut away. The gold keeps working down or dropping into them, and thus it moves almost vertically downwards with the deepening of the valley. In this way a streak or band of rich gold-bearing gravel would be formed in the bottom of the narrow valley, distributed in the crevices of the rock and in protected places immediately on top of it.

After the stream had cut the bottom of its valley down to grade or base level, and had ceased the process of vertical erosion, it would begin to cut laterally and to widen the bottom of the valley so formed, and to deposit sand and gravel in the form of flood-plains on it.

During this process of lateral erosion, the gold, which had already been collected from all the surrounding country into the bottom of the V-shaped valley, would be, to a large extent, below and out of reach of the influence of the meandering stream with its slower current. The stream would, however, continue to widen its valley and to extend its flood-plain and in many cases to build this flood-plain up to greater and greater thickness.

In this way we can see how such pay-streaks as that of the White Channel gravels of Bonanza Creek have been formed. They represent the gold collected in the



**Crystals of Gold from Victoria Gulch.—Magnified 2½ diam.**

old V-shaped valleys of that period, while the great thickness of gravel above and on both sides of them was deposited after these pay-streaks were formed.

Gold is usually not entirely absent from the upper and lateral gravels, for some of the precious metal was being constantly washed down from the adjacent hills with pebbles of quartz, schist, and other rocks; but the coarse gold of the pay-streak on and in the bed-rock was collected into its present position before the gravel was deposited on top of it, and it was not concentrated out of the gravel above it, as has often been assumed.

It may therefore be accepted as a definite law, that pay-streaks were formed on, and indicate the positions of, the bottoms of old V-shaped valleys.

If the bottoms of the present valleys are much wider than the paystreaks, this greater width represents the amount to which these valleys have been cut out by lateral erosion after they had been originally outlined to their present depth, and the gravels with which these valley bottoms are covered are later in age or newer than the pay streaks.

For instance, the old pay-streaks in the White Channel gravels on Bonanza and Hunker creeks which are well shown on Mr. McConnell's map accompanying his "Report on Gold Values in the Klondike High Level Gravels," run in very straight lines approximately down the middle of the old valleys, though possibly a little nearer their western than their eastern sides. The outlines given on that map for the approximate original boundaries of the White Channel gravels show the widths of the old flood-plains, and the extent of the gravels deposited over and around the pay-streak. The pay-streaks mark the positions of the bottoms of the original V-shaped valleys, and the gravels are flood-plain deposits which were subsequently laid down over and around them.

Similarly the pay-streak can be traced down the bottom of the present valley of Bonanza creek, marking the line of the bottom of the old V-shaped valley. In places this old valley bottom at one time crossed terraces in the present valley and then short strips of the pay-streak were left across these terraces. Later as the stream deepened its valley the botom swung round the terraces. Very often the pay-streak is not so rich around these curves, for it had to start anew without any gold to work on. The gold which is contained in this new portion of the pay-streak is not that which descended vertically with the growth downwards of the valley, but is rather that which was brought down the valley by the stream after the terrace was formed, or the little which was brought into it from the sides.

At the present time I am collecting information on the presence of these low terraces and their influence on the value of the pay-streak in the adjoining deeper valley; but the matter is not yet ready for publication.

In this connection attention may be drawn to the fact that while the gold and the heavy minerals associated with it in the pay-streak represent a concentration from the whole of the material first eroded from the Dome Peneplain, that in the overlying and surrounding gravel only represents a concentration from the surface of the country after the present valleys were cut down to base level at practically their present depths, and after flood-plains began to form in them.

It may also be interesting to point out that the law above annunciated, namely, that the pay-streak marks the bottom of the old V-shaped valley, should be of interest to all students of physical geography, since, wherever it can be found, it furnishes a datum line from which the growth of the valley outwards can be followed and studied. Even where a pay-streak carrying gold is not present in a valley, a band of heavy minerals or coarse rock fragments might be detected which would indicate the original position of the bottom of the V.

It is not improbable that gold may have a tendency to settle down through gravels and to collect on bed-rock below them; but this tendency exerts a minor influence in the formation of workable placers.

In McConnell's Report, pages 9 and 10, the gold values per cubic yard of two columns of gravel are given, taken from the hills beside Bonanza and Last Chance creeks, one 159 feet high and the other 90 feet high. These columns were unfortunately taken over the pay-streaks in which the gold existed before the gravel was deposited over it; but omitting the lowest 6 feet in each column which appears to contain the pay-streak, the rest shows an increase in value downwards, in the one case from .6 cent to the cubic yard to 18 cents a cubic yard, and in the other from .7 cent to the cubic yard to 11.4 cents to the cubic yard.

In the first column the total amount of gold contained in the upper 51 yards is $1.27, while the lowest 2 yards contained $8.26. In the other column the upper 28 yards contained $1.07, while the lowest 2 yards contained $4.40.

These values may give some indication of the relative amount of gold which was concentrated into the valleys, first, in the earlier stages of erosion when the pay-streak was formed, and the lighter material was carried away, and secondly, in the more mature stages of erosion, when the pebbles of quartz and other rocks were deposited with the gold.

The upper gravels probably contain almost all the gold that was eroded out of the rocks of the surrounding country while these gravels were being deposited, and if we knew the relative sizes of the particles of gold in the gravels and in the pay-streak, we might be able to form some idea of the percentage of the gold which had been worn out of the rock of the country and had been collected in the pay-streak; but unfortunately this information is not available at the present time. However, it is quite certain that the gold in the gravel is, on the average, much finer than in the pay-streak, and as the gravel gold doubtless represents closely the general character of that contained in the country rocks, we must assume that in the pay-streak much of the finer gold has been carried away, and that the coarser particles are all that have been left. It is hoped that it may be possible to compare these two runs of gold more fully at some future time.

If the erosion of a valley were to continue downwards uninterruptedly in rock of similar character throughout until its bottom should have reached base level before the stream which formed it began to erode laterally, the gold would be distributed in a continuous line along the bottom of such a valley and when the stream had afterwards widened it and had formed alluvial flats and flood-plains the pay-streak would be continuous through and under these alluvial flats.

But streams rarely, if ever, deepen their channels uninterruptedly in this way. Harder bands of rock cause obstructions, and elevations and depressions of the land cause the water to flow with different velocities at different times, so that at one time, or in one part of its channel, a stream may be cutting into the bottom of its valley, while at another time and in another part of its channel it may be filling it up and covering it with alluvial sand and gravel

In this way a stream with a valley of any considerable depth has probably formed a number of flood-plains at different periods in its history, and remains of these flood-plains may often be seen as terraces on the sides of its valley.

When a stream has formed a flood plain the pay-streak will, as we have seen, run beneath that flood plain on a line marking the original bottom of the old V-shaped valley and if, when the stream again begins to cut through this flood plain and into the rock beneath it, it follows the line of the former stream, or, in other words, if it follows the line of the pay-streak, it carries the pay-streak down with it; but if it diverges from this line, a portion of the pay-streak remains on the terrace. If it continues to deepen its channel until all the terrace is removed, or at least until that portion of it is removed which contains the pay-streak, the gold will also all be in the pay-streak in the bottom of the new valley; but if it reaches a new base level before the pay streak is all removed from the terrace a new condition is introduced. The stream may begin to cut into the side of its valley and may cut into and remove the old terrace containing a portion of the old pay-streak. In that case, the gold may drop down into the bottom of the valley with the eroded rock and gravel and form a rich pocket at one side of, and often quite off the line of the original pay-streak or it may be distributed along the channel which the stream happens to be following at the time. If the renewed stream happens to cut in to the old valley bottom to one side of the original pay-streak, or across it at several places and to diverge from it at a number of other places, the new pay-streak may be weak and indefinite, or it may be rich in spots and very poor between those spots, with other rich spots to one side or the other. In fact, it may assume a variety of characteristics, according to the manner of growth of the valley in which it has been formed.*

From these considerations it may be seen that continuous and regular formation of a valley will tend to the existence of a regular pay-streak, while discontinuous and irregular growth of a valley will form an irregular and disjointed pay-streak with many lateral apophyses.

In some cases it may happen that the rejuvenated stream will abandon the old valley altogether and in this way be removed from the influence of the old pay-streak. An example of this condition occurs on the lower portion of Bonanza creek, where, at about claim 80 below Discovery, the new valley leaves the old one, the stream having turned westward to cut out an independent channel through the country rock. As the creek during this later stage of its existence gathered but little gold from the rocks of the surrounding country, but rather depended for the richness of its placers upon that which had already been collected into the pay streak of the White Channel period, and as in leaving the old valley it had here left this old pay-streak entirely, the gold which occurs on this lower portion of Bonanza creek has either been carried down the creek itself from the higher parts of its valley, or has been brought into it by the stream flowing from Lovett Gulch which taps the White Channel pay-streak. The pay-streak is consequently not as rich here as it is farther up Bonanza creek, where it is directly beneath the former position of the old White Channel pay-streak, and contains much of the gold which that pay-streak formerly contained.

When we recognize that a pay-streak was formed in the bottom of a V-shaped valley at a time when that valley was being actively deepened, and when the bottom of the channel of the stream was composed of hard unweathered rock of the country, we can readily appreciate the influence that the character of the rock would have on its richness or poverty.

If the rock were hard and smooth the gradient of the stream would in that case continue higher than the average until base level had been reached throughout, the current would consequently be stronger, and the gold and coarse gravel would tend to be carried down to a more favourable location for settlement.

If, on the contrary, the rock were soft and fissile the gradient would be lower than over hard rock. the current of the stream would be slacker and the gold would have a better opportunity to settle down into the fissures and points that form riffles to collect it.

The conditions would be similar to those in a sluice-box. If the water flowed over a smooth bottom the gold would be carried away, and if it flowed over a rough and broken bottom with many openings in it, the gold would settle down in these openings.

As the stream cuts down into the bottom of its valley it will not under ordinary conditions, again pick up this gold that has settled into the fissures, except in cases where the supply of gold becomes too great for the natural riffles to hold, but rather as the surface of the rock is gradually worn down by the stream, the gold will be allowed to settle deeper and deeper below its original point of sedimentation. For instance, if gold particles have settled in fissures in a schistose rock these particles will continue to sink vertically for hundreds of feet if the fissures continue to persist, as long as the stream continues to deepen its channel on the same course.

**Character of the Gold.**—The general character and value of the gold found in the Klondike has been given in Mr. McConnell's "Report on the Gold Values in the Klondike High Level Gravels" and need not be repeated here. It all contains a considerable percentage of silver, but the quality varies to such an extent in different places that while the value of the gold on parts of Dominion creek is as high as \$17.75 an ounce some of that from Last Chance creek is not worth more than \$12.50 an ounce. The average value of the gold exported from the Klondike in 1905 was \$16.02 an ounce after it had been melted.

That in the bottoms of the valleys is generally well rounded and water-worn, or perhaps it would be more correct to say beaten round while it had been carried along by the water. But much of the gold in the White Channel gravels is more or less angular, and some of it is quite clearly crystaline. Many of the crystals are feathery and very delicate, and it is possible that some of these may have been deposited on the sides of other fragments, or around nuclei through the agency of water carrying gold in solution, which percolated downwards through the overlying gravel. But other crystals were undoubtedly formed in quartz veins and have been mechanically removed to the positions which they now occupy in the gravel. Those represented on Plate II are clear examples of this class. Figures 1 and 2 are two views of a twinned octahedron. Figures 3 and 4 show a cube with hollow faces and with the angles modified by the faces of the rhombic dodekahedron. Other crystals found by the writer have already been

*See paper by the same author on The Law of the Pay-streak, with illustrations, in Trans. Inst. Mining and Metallurgy, Vol. xxi (1912) pp. 593-605.

recorded by Professor Miers. They occur in a vein of quartz at the head of Victoria Gulch, and similar crystals have also been washed out of the gravel on some of the mining claims on the Gulch itself. They are octahedral twinned parallel to the octahedral face, and are usually in the shape of flattened triangular plates. Those shown on Plate I were obtained from Mr. Philip Holloway's claim Number 7, on 7 Pup, Victoria Gulch where Mr. Holloway very kindly allowed me to sort over his gold and take away these crystals.

**Associated Minerals.**—The minerals associated with gold in the camp are the following: Meteoric iron, native copper, graphite, magnetite, haematite, pyrite, cassiterite, quartz, rutile, garnet, epidote, kyanite, scheelite, awarnite, almandite, etc.

**Production.**—The ordinary creek claims in the Klondike had a length of 500 feet up and down the creek, and several of these yielded more than a million dollars, or an average of more than two thousand dollars to the running foot. Fraction A on Bonanza creek, at the mouth of Skookum gulch, had a length of 86 feet, and Richard Low, the owner, informed me that he had extracted gold to the value of between half and three-quarters of a million dollars from it, giving an average yield of from $5,800 to $8,700 a running foot of the claim. I was present at one clean up on this claim, after thirty hours' work by six men, and the clean gold recovered filled eight gold pans as full as it was possible to carry them without breaking.

Up to the present time placer gold mining in the Yukon territory has produced gold to the value of $140,879,500, about 99 per cent. of which has been taken from the Klondike district.

As we have shown this gold has been concentrated by ordinary stream and atmospheric agencies into the bottoms of the valleys from the rocks of the surrounding and adjoining country. As far as we know, it was first concentrated into the bottoms of the valleys of the White Channel period or Second Cycle, and part of it was again reconcentrated into the bottoms of the valleys of the Third Cycle.

Altogether there has been removed since the age of the Dome Peneplain about 136 cubic miles of rock, and the gold which was contained in these 136 cubic miles has, to a large extent, been concentrated into the pay-streaks and gravels in the bottoms of the valleys. The exact proportion of gold that has been retained in the valleys and that which has been carried away is not known, but the two hundred million dollars worth or ten million ounces of gold which was retained in the valleys would, if evenly distributed through the rock from which it was derived, amount to .013, or approximately 1/75 of a cent to the ton. It is thus clear that the Klondike placers owe their richness entirely to the peculiarly favourable conditions of concentration which have existed through a long period of time in that unglaciated district, rather than to any particular richness of the rock from which the placers were originally derived.

Another feature of interest may be worthy of mention. The rocks in the Klondike are schists and slates of pre-Cambrian age, such as are generally recognized as being favourable to the occurrence of gold-bearing veins. Many quartz veins occur in these rocks, and in many of these quartz veins gold is distinctly visible, while in other veins it can be recognized in small quantities by assaying. The rock of the country is therefore distinctly a gold-bearing rock.

One hundred and thirty-six cubic miles of this gold-bearing rock were put through nature's mills and the gold contained in it was concentrated in nature's sluices, and from it a total of ten million ounces of gold, worth about two hundred million dollars, was extracted, proving the rock to contain an average gold content of at least 1/75 of a cent to the ton. What percentage of the gold contained in the original rock was saved we do not know; but if nature's concentration processes were not grossly inefficient the average gold contents of the gold-bearing pre-Cambrian rocks of the Klondike must have been very low.

---

# NOTES ON THE SAN FRANCISCO MILL, PACHUCA, MEXICO*

By J. P. Holcombe, Student.

Some notes on this mill may be interesting, not only because it was the first cyanide mill erected in Pachuca, but also because it was the pioneer mill, in the western hemisphere, to use the Brown agitating tank, since called the "Pachuca" tank in America.

Originally built as a pan amalgamation custom mill, it was taken over by the Maravillas Mining Co. in 1910, since when both mines and mill have been worked under the same management.

The whole plant has been electrically equipped throughout, the power being supplied by the Mexican Light and Power Company from their hydraulic plant at Necaxa, some 90 km. (about 56 miles) away.

The capacity of some of the motors is much greater than is now required, owing to constructional changes in the past.

After many alterations the mill now consists of three 10 in. × 12 in. Blake rock-breakers; one 16 in. × 22 in. set of rolls; forty 1,250 lb. stamps; eighty Wilfley concentrators; four Dorr classifiers; three 13 ft. × 4 ft. 6 in. Krupp and one 15 ft. × 5 ft. Denver Engineering Works tube-mills; four 10 in. × 54 in. Frenier pumps; four Dorr pulp thickeners, three of these 24 ft. × 10 ft., and the fourth 30 ft. × 10 ft.; eight "Pachuca" tanks 45ft. × 15 ft.; two 22 in. bucket elevators, buckets set 18 in. apart; one Moore vacuum filter (movable type) with the necessary sumps, solution tanks, pumps, pulp storage tank, compressors, etc.

The ore, which comes from several mines and dumps varies in character a great deal, the value being chiefly in the form of silver sulphides, with some manganese, galena, zinc blende and pyrites, these latter being eliminated to a great extent by coarse concentration. The mill-heads for the past six months averaged 595 grm. (19.12 oz.) of silver, and 2.84 grm. (0.091 oz.) of gold per metric ton (2,204 lb.).

*From the Bulletin of the Institution of Mining and Metallurgy.

The ore is received in the "patio" or yard adjoining the mill, where it is weighed, and then trammed to the rock-breakers and rolls situated immediately above the ore-bin, which holds 450 metric tons. After passing over a grizzly of 2 inch spacing, the coarse ore is crushed to pass a 2½-inch ring, the rolls acting as a fourth primary crushing machine with distribution by means of a 18-inch Robins conveyor belt.

The ore is fed by "Challenge" feeders to the stamp-mill, which is driven from one line shaft by a 200 h.p. motor; the stamps make 100 drops per minute, the height of drop being 7 inches. The mortars stand on concrete blocks which extend to the masonry of the ore-bin, thus making a very substantial battery foundation and feeder floor. The screens in use have either six or eight holes to the linear inch, according to the class of ore treated.

Crushing is done in cyanide solution, and the pulp, after leaving the stamps, is concentrated on "Wilfley" tables, about 14 per cent. of the value being obtained by concentration. It then flows to the Dorr classifiers, the sand to be ground and re-ground in the tube-mills; the overflow, which for all practical purposes may be considered as slime, being conveyed direct by elevator to the cyanide plant. There are no cones in the mill.

The concentrate is conveyed by pipes directly from the tables to sumps in the concentrate storage room lower down the mill, thus obviating chances of theft and saving labour, the clear overflow from these sumps joining the mill solution.

The three Krupp mills make 28 revolutions per minute, being driven from one line shaft by a 200 h.p. motor, and the Denver mill, 26 revolutions per minute, by a separate motor of 75 h.p. The battery motor and the large tube-mill motor are so placed that, in case of a breakdown of either, one-half of the mill can still be run by mounting belts on pulleys, which are always in position on the battery line shaft and tube-mill countershaft. One motor drives the Frenier pumps and Dorr classifiers.

The stamps have a much greater capacity than the tube-mills, this fact explaining the low stamp duty, which for the past six months has averaged 5.570 metric tons per 24 hours.

The tube-mill feed is kept as thick as possible and contains about 35 per cent. moisture as it enters the scoop feeder. The Denver mill does better work than the others. The four mills are fitted with "El Oro" lining and mine rock only is used, it being fed as large as possible through a 6½-inch spiral while running. Formerly, imported flint pebbles only were used, then different proportions of pebbles and rock were tried, but the so-called selective action of the former in remaining in the ribbed lining was not apparent, and for the last year nothing but mine rock has been used. Even considering loss of time due to re-lining and extra expense of new liners, the difference in cost between the use of pebbles and mine rock is greatly to the advantage of the latter in this mill. The mills are kept as full as possible with rock, the consumption being 30.7 kg. (67.5 lb.) per ton of ore ground. This rock contains approximately 200 grm. silver (6.43 oz.) and is included in the mill tonnage.

The average life of locally-cast white iron liners is 8.5 months. Experiments are now being made with liners containing 25 per cent. steel, but no data are yet available. The pulp delivered to the cyanide plant averages 80 per cent. through 200-mesh screen.

All the tube-mills are placed in one line, end to end, with a space of 4 ft. between the discharges of Nos. 1 and 2, and 3 and 4, one man attending to the feeding of rock to two tube-mills. One 48-in. × 10-in. Frenier pump returns the discharge from two tube-mills for re-classification.

The overflow from the Dorr classifiers, having a consistency of 8 to 1, is elevated by an elevator with a belt speed of 250 feet per minute, and is discharged through pipes to the Dorr thickeners; the clear overflow from three of these joins the mill solution and that from the fourth is precipitated. The pulp from these thickeners has a consistency of 1.2 parts of solution to 1 of ore, and flows by gravity to the "Pachuca" tanks, where sodium cyanide is added to bring the strength of solution up to 0.4 per cent. potassium cyanide. The protective alkalinity is kept at about 2 lb. CaO per metric ton of solution, by adding lime to the tube-mill feed, the consumption being 4.4 kg. (9.7 lb.) per metric ton of ore.

Each tank is filled separately, and when filled, titrated and sampled, agitation is maintained for 36 hours, then follows a rest for 10 or 12 hours, after which as much agitation as time will allow before filtering.

While describing these tanks, I may say that the experiment of removing the top length, measuring 13 feet of the central column, has been tried on one tank for several months, giving no apparent benefit. Also for the air lift, plain unprotected nipples, 15 inches long, are in use in all these tanks and have not given any trouble.

No lead acetate is used in the "Pachuca" tanks, but an amount equal to 300 grm. (0.66 lb.) per metric ton of ore crushed, is added to the mill solution at regular intervals. The consumption of potassium cyanide per ton of ore crushed is 834 grm. (1.83 lb.).

The pulp after treatment is pumped by centrifugal pumps to the storage tank which feeds the filter plant.

One basket of 40 leaves is constantly working. There is a complete spare basket, also spare leaves. The working leaves are given an acid bath every month. This filter treats, with one basket only in use, 220 tons of ore per 24 hours; it started working 13 months ago, and has given very satisfactory results. The cakes are discharged by water under a 20-ft. head.

A cycle is as follows:

| | Minutes |
|---|---|
| Making cake 1¼ inches | 20 |
| Transfer to barren solution tank | 3 |
| Barren solution wash | 40 |
| Transfer to water and discharge tank | 3 |
| Water wash | 15 |
| Discharging cake | 5 |
| Total | 86 |

The filtered strong solution, and the first ten minutes or so of solution wash, is pumped to the pregnant solution tanks for precipitation, afterwards joining the mill solution, the rest of the solution wash being precipitated apart, then returned to the filter for cake washing.

The precipitation and melting house contains ten 5-compartment zinc boxes, each compartment being 36 inches × 33 inches × 39 inches high, above the trays where 4-mesh screen is used. Nine of these boxes are packed with zinc, and a clean-up is made every week. The zinc consumption per kilo of bullion produced is 1.101 kilos (2.42 lb.). Precipitation is good, the zinc box effluent hardly ever reaching 2 grm. (30.8 gr.) of silver per ton of solution. All zinc washing is done in solution, the discharge from the precipitate press being pumped to the head compartments of two zinc boxes.

The precipitate is washed through a 40-mesh screen and pumped into a ½-ton Shriver press; it is given no acid treatment, contains 80 per cent. to 85 per cent. bullion, and is discharged after passing compressed air through it for 20 minutes, the precipitate then containing about 28 per cent. moisture. There is a strong-room in which the car containing the precipitate is kept overnight for melting the next day. There is also a bullion safe inside the strong-room.

Originally there were six coke furnaces, but three of these have been converted into oil furnaces with good results. Morgan No. 300 crucibles are used, and the flux is borax glass 7 per cent., soda ash 5 per cent., lime 1 per cent., and sand 2 per cent. With this flux the bars assay from 910 to 940 fine in silver, with four to five parts gold, and weigh from 32 to 35 kilos (70.4 to 77 lb.) each.

The consumption of fuel oil per kilo of bullion produced is about 1.49 litres (0.328 gall.).

The air compressor equipment is as follows:

One Ingersoll-Rand duplex, class "J," simple air cylinders, 12 in. × 14¼ in., making 160 revolutions per minute, capacity 595 cubic feet per minute.

One duplex Ingersoll-Rand, 16 in. × 10 in. and 10 in. × 10 in. (converted compound), making 130 revolutions per minute, 675 cubic feet of air per minute.

One Ingersoll-Rand type XI., vertical, capacity 270 cubic feet per minute.

One of the first two supplies enough air for the agitation of six Pachuca tanks, one pulp storage ("Pachuca" type) and pulp tank of Moore filter, also blacksmith's shop. A pressure of about 30 lb. per square inch is maintained. When the melting furnaces are used the type XI. compressor also runs.

The average cost per metric ton of ore milled during the period January to June last, was as under:

| | | |
|---|---|---|
| Rockbreakers | $0.11 | 2.64d. |
| Batteries | 0.24 | 5.76 |
| Concentration | 0.04 | 0.96 |
| Tube-mills and classifiers | 0.29 | 6.96 |
| Agitation | 1.05 | 25.20 |
| Filtration | 0.16 | 3.84 |
| Pumping | 0.09 | 2.16 |
| Precipitation and melting | 0.41 | 9.84 |
| Sampling and assaying | 0.13 | 3.12 |
| General repairs | 0.17 | 4.08 |
| Surface expenses | 0.05 | 1.20 |
| Power | 0.81 | 19.44 |
| General expenses | 0.31 | 7.44 |
| Total | $3.86 | 92.64d.=7.72s. |

A Mexican peso is approximately 2s.

The actual extraction during this period was 92.4 per cent. of the silver, and 94.5 per cent. of the gold.

With the exception of the superintendent, day and night foremen, and precipitation house man, who are all English, local Mexican labour is employed throughout the mill.

## U. S. COAL MINE ACCIDENTS

The coal-mine accidents occurring in the United States during the year 1912 have been compiled by the United States Bureau of Mines under the direction of Frederick W. Horton. The publication which is now ready for distribution gives a resume of the accidents from 1896 to 1912 inclusive with monthly statistics for the year 1912.

Mr. Horton in reviewing the year says: "During the calendar year 1912 there were 2,360 men killed in and about the coal mines of the United States. Based on an output of 550,000,000 short tons of coal produced by 750,000 men, the death rate per 1,000 emplayed was 3.15 and the number of men killed for every 1,000,000 tons of coal mined was 4.29. The number of men killed was the least since 1900, the death rate per 1,000 employed was the smallest since 1899, the death rate per 1,000,000 tons of coal mined was the lowest, and the number of tons of coal produced in proportion to the number of men killed was the greatest on record. These facts offer indisputable evidence that conditions tending toward safety in coal mining are actually improving and that coal is now being mined with less danger to the miner than ever before. The general improvement in 1912 as compared with 1911 is shown by the following facts:

"In 1912 the number of men kileld in the coal mines of the United States was 339 less than in 1911—2,360 as compared with 2,719—a decrease of 13.2 per cent., and this in spite of the fact that there were more men employed in the mines and more coal mined than in any previous year.

"The death rate per 1,000 men employed in 1912 was 3.15, as against 3.73 in the previous year, a decrease of 15.5 per cent.

"During 1912 for every 1,000,000 tons of coal mined 4.29 men were killed, as compared with 5.48 men in 1911, a decrease of 21.7 per cent.

"There was 233,000 tons of coal mined for each man kille din 1912, as compared with 183,000 tons in 1911, an increase of 50,000 tons, or 27.3 per cent.

"Although the improvement in 1912 was greater than in any previous year for which accurate statistics are available, partly due, perhaps, to exceptionally mild weather during the last few months of the year decreasing the likelihood of disastrous coal-dust explosions, there has been an annual improvement for a number of years, as indicated by the accompanying table:

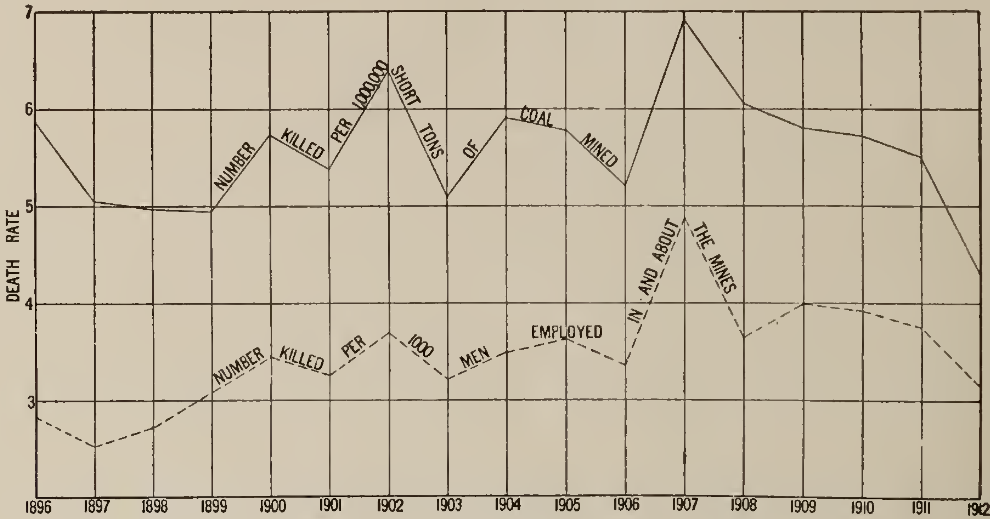
Number of men killed in and about the coal mines of the United States in the calendar years 1907 to 1912, inclusive, with death rates:

| | Number Killed | | | |
|---|---|---|---|---|
| Years. | Total. | Per 1,600 employed. | Per 1,000,000 short tons mined. | Production per death short tons. |
| 1907 | 3,197 | 4.88 | 6.93 | 144,000 |
| 1908 | 2,449 | 3.64 | 6.05 | 165,000 |
| 1909 | 2,668 | 4.00 | 5.79 | 173,000 |
| 1910 | 2,840 | 3.92 | 5.66 | 177,000 |
| 1911 | 2,719 | 3.73 | 5.48 | 183,000 |
| 1912 | 2,360 | 3.15 | 4.29 | 233,000 |

"It will be noted from the foregoing table that the death rate per 1,000,000 tons of coal mined has decreased annually, that the production per death has increased each year since 1907, and that the death rate per 1,000 men employed has steadily decreased during the last four years.

"This general improvement has been brought about by a combination of causes, the principal one of which has been more efficient and effective mine inspection on the part of the State mining departments and State mine inspectors throughout the country, supplemented by greater care on the part of both the operators and the miners. The investigative and educational work of the Bureau of Mines has kept both the operator and the miner alive to the various dangers connected with coal mining and has shown what precautions should be taken to avoid these dangers. The bureau is therefore gratified with the improvement shown, particularly as the greatest improvement relates to dangers concerning which the bureau has been conducting special investigations, as is shown later. The bureau, however, can not too strongly express its appreciation of the co-operation of the State mining officials and the operators in the work of making coal mining safer.

"Although there has been an annual improvement in mine-safety conditions since 1907, and a particularly notable one in 1912, a still greater decrease in the death rate can be effected. Whether or not such an improvement will be made in 1913 depends largely on the care exercised by the operators, superintendents, foremen, and all others in authority, and by the miners as well, to prevent the rise of dangerous conditions and to avoid unnecessary risks when such conditions have arisen."



Death rate per 1,000 men employed and per 1,000,000 short tons of coal mined for the years 1896 to 1912.

Copies of this report, Technical Paper 48, may be obtained by addressing the Director, Bureau of Mines, Washington, D.C.

# MOTOR FOR STAMP MILL DRIVE

A special motor for driving stamp mills has been recently placed on the market by the Westinghouse Electric and Manufacturing Co. after thorough tests in actual service have proved its suitability for this work.

The motor is mounted in a cradle which in turn is mounted on a heavy base plate. The cradle carries a back shaft to which the motor is geared. The back shaft pulley runs at slow speed so that it can be belted directly to the bull wheel of the stamp mill, thus eliminating the jack shaft and saving space, belting, the loss of power due to belt slippage, and the expense of maintenance of the jack shaft. The motor cradle can be slid along the base plate for belt adjustment, an especially long range of adjustment being provided.

The pulley is outside the bearing on the cradle so that the belt can be easily removed. The motor, gear and pinion can be removed without disturbing the line-up of the pulleys or handling the belt. The back shaft bearings are split and can be inspected or renewed after merely slackening the belt. The gears are enclosed in a dust-proof case and run immersed in oil.

The motor itself is extremely strong and rugged and is built to withstand the very severe service encountered in stamp mill drive. It is of the type originally designed for steel mill work where the worst operating conditions found in any industry must be successfully withstood.

This outfit can be supplied for driving mills of from 3 to 20 stamps, with stamps weighing from 80 to 1,250 pounds. One motor is ordinarily used for each battery and is shut down when the battery is not in use, thus avoiding a waste of power.

# SURF INLET GOLD MINES.

The following information concerning the Surf Inlet gold mines was recently contributed to the B. C. Mining Exchange, Vancouver, B.C., by Mr. Fred M. Wells, and is reproduced here for the reason that several Eastern investors were at one time interested:

The Surf Inlet gold mines are situated on Princess Royal Island on the coast of British Columbia, about 400 miles north of Vancouver City. The island, which is about 60 miles long and 25 to 30 miles wide, is a mass of rugged mountains with heavily-timbered valleys and beautiful fresh-water lakes, making it an ideal country to live in and operate mines.

The first discovery of gold quartz here was made many years ago by an Indian who reported the find to some Victoria people. An investigation was made, this resulting in the discovery of the quartz vein and location of the ground now known as the Princess Royal mines. Eastern people became interested in the property and a large amount of development was done. Ore was mined and shipped in small quantities, but eventually the work was given up because it did not return a profit. This gave the camp a "black eye," and for some years it was difficult to get mining men to visit the camp to investigate for themselves the merits of the mines.

It is not for me to say what was the real cause of the failure, but I understand the ore was sorted, packed out to salt water on horses, and shipped to the smelter. I am sure no profit could be made on the ore in that way, and I suggest that this was the cause of the failure. The owners had nice ore, and I feel sure a small mill installed on the ground would have made for them the success the eastern investors expected.

During the operation of the property some miner traced the fault line across the creek and up the mountain side opposite Princess Royal camp, and discovered the large outcroppings of ore that are now the Surf Inlet gold mines. In some way Mr. E. A. Cleveland, civil engineer, of the firm of Cleveland & Cameron, of Vancouver, became interested in the property and attempted in a serious way to make a mine out of it. About this time the work was closed down on the Princess Royal claims and Mr. Cleveland, being unable to interest capital to assist in continuing development, finally closed the camp down. About four years later the camp was brought to the notice of Mr. A. B. Clabon by some interested parties in the East, and it was arranged that I should make the trip in to examine both properties.

Late in the fall of 1909 I made the trip, and spent about ten days in the camp, and after returning to Vancouver secured from Mr. Cleveland an option for Mr. Clabon and myself. In the following spring I took in some men over the snow on snowshoes and commenced work under our bond. The results were so good that we at once formed the Surf Inlet Gold Mines Co., interesting in it prominent Vancouver business men, who have carried on work continuously since that time.

Though we are isolated from steamer routes, we have a regular force of 12 to 15 men working. Our camp is well equipped, and includes a complete assay outfit with an assayer on the ground, who keeps us informed on the value of the ore as developed—a necessary thing in a gold camp.

The country formation of Princess Royal island is mostly granite, locally called "coast" granite, rather dark in colour and somewhat stratified. The ore bodies are well defined and were formed along a great fault line. The fault has been subjected to much shearing and crushing along its course. The effect of this great rock movement has been in places very marked, brecciating and altering the granite rock for a distance of from 50 to 100 feet from the main fracture. The ore is a hard rose quartz, containing iron pyrite, outcropping boldly where cut by small creeks.

Work has been done and ore proven for some miles along the fault line, but no large amount of work except on the Surf Inlet Gold Mines Co.'s property, and the adjoining claims on the south belonging to the Princess Royal company.

There are often two parallel veins, and where the altered rock exists these veins or ore shoots seem most apt to form along the outer sides and in the contact of the solid granite and the altered rocks. The country has been very much eroded by glaciers, which have left a hard and unoxidized surface to all ore outcroppings, practically doing away with surface accumulations of value from weather effects. From a close observance of the ore as development attains depth, I would say that there was no re-enrichment of these veins near the surface, and that the gold value at present established will be permanent.

The quartz veins so far developed are rather small, except on the Surf Inlet property the vein on which has been proven to be from 10 up to 20 feet in width.

A strong feature of this mineral belt is that there never seems to be barren quartz bodies. The value may go low, and it does in places, but wherever a shoot of quartz exists it is safe to figure on gold value sufficient to pay to mine, while the better-grade ore at times runs up to $100 a ton, and even higher, often showing free gold specimens.

### Development.

On the Surf Inlet property there are two veins, called respectively the east and west veins. The west vein is running at such an angle that we expect it to make a junction with the main vein at some point ahead of our present workings. Both of these veins have been cut to some depth by a small creek, and development of each has been by drifting on the vein from this creek. The wets vein has been drifted on for 150 feet, and the vein cross-cut in several places, proving an ore body from 4 to 10 feet wide, and sometimes containing remarkably high gold value, with an average of about $20 a ton.

At a level of about 150 feet vertically below this work the No. 2 tunnel was driven on the main vein. This drift has just reached the 630 foot mark; it has continued on ore all that distance and has proved a most valuable gold ore body. It has been my practice to drive the tunnel along the footwall side of the vein wholly or partly in ore and then, at intervals of 50 feet cross-cut to the hanging wall.

Throughout all this work the vein is shown to be a perfect type of fissure vein, and to vary in width from 10 to 29 feet. This tunnel attains a depth of 400 feet following the vein. A shaft has been sunk on the vein from the surface to a depth of 50 feet and cross-cut at the bottom shows the width of the vein there to be 18 feet.

At about the 150-foot mark in the tunnel a cross-cut shows the vein to be 16 feet wide, at 350 feet in it is fully 15 feet, at 400 feet the width is 12 feet, at

450 feet, 20 feet, with not less than 10 feet at any place cut up to the 600 foot cross-cut, just completed and showing a width of 20 feet of clean ore. This is the deepest point yet developed in the mine, and the orebody seems to be the largest and containing best average value. Carload samples of ore from this cross-cut run as high as $35 per ton, while the orebody will average about $15 in gold, for the 20 feet. I estimate the average width of this vein at 12 feet, which is easily inside the mark.

At the present time we are pushing the main drift ahead along the ore body and raising to the bottom of the 50 foot shaft, a height from No. 2 tunnel of more than 200 feet. This rise will prove the orebody between the level and bottom of shaft and serve to give air to our workers below.

A cross-cut has been driven from the main tunnel to cut the west vein at this level and prove the ground between. Ore has been encountered, but we are not sure at present whether it is the real vein or not. Some remarkably high value has been obtained, but it is possible the larger orebody has not yet been reached by this cross-cut.

### Orebodies.

While at the 600-foot cross-cut the orebody is large, it is still probable the west vein is somewhere nearby, and in the hanging wall of the altered rock belt, which at this point is probably about 100 feet thick. It is my intention to make a thorough cross-cut to the solid granite by continuing the 600-foot cross-cut, which will prove this point.

The oreshoot is proven to be more than 700 feet long, and the strongest showing developed is the deepest down and farthest into the hill. It is impossible to say how much farther this shoot will continue without a break, but there is no good reason for it to give out for some distance.

On the contrary some of our best surface territory is on ahead, and I believe after machines shall be installed large orebodies will be developed in that direction by following the sheared zone, as we are at present doing with such good results.

The company's ground covers nearly a mile in length along the fault line, all of which will be developed in time, and no doubt the finding of many good oreshoots will be the result.

The present tunnel level is several hundred feet above the creek, so several lower levels can be driven with moderate cost for amount of ore such work would develop.

While it is true that until the rise is completed there is not much ore technically developed, yet with an orebody of this character and proven to be so well defined, much latitude can safely be allowed an engineer in attempting an estimate of ore developed. Presuming that the vein as shown in all the development work is to be a fair average of the ore through to surface, there should be at least 150,000 tons of ore above the No. 2 level. The orebody averages stronger throughout the tunnel than the surface showings, so I think ore figured below this tunnel for a reasonable distance perfectly safe base to reckon on. If you allow the first 100 feet below you have 70,000 tons, making 220,000 tons practically in sight to begin milling on, and this is without bringing the ore in the west vein into the calculation.

Regarding the value, which is all in gold—while some parts of the vein are low there are no barren areas, and to offset the low parts some rich ore occurs. Ore $8 to $10 a ton is most common, and we hope to make a mill-feed average of about $10.

### Ore Treatment.

The treatment of the ore has been given some exhaustive tests during this season. The last test was made on a one ton sample taken from all parts of the orebodies. This was placed in the hands of Mr. C. E. Verrill, an expert mill man of Vancouver. This ore was tested in the works of Messrs. Falkenberg & Lucks, Seattle, Washington. These tests have been perfectly satisfactory, and they have resulted in determining the simplest method of treating the ore and making about the highest saving known on any plant.

The ore contained fully 10 per cent. iron sulphides, in a brittle and clean quartz, which admits of a very clean concentration, but it was found that both the iron sulphides and the quartz sands yielded a higher saving by simple cyaniding. So test swere made of fine grinding the straight ore and cyaniding the whole product. This gave such good results that this simple process has been recommended to the company.

# THE PULMOTOR IN MINE RESCUE WORK.

By Henry E. Bertling.*

The need for an improved substitute for mechanical resuscitation has been felt for a long time, medical practice offering a wide field for such experiments in the frequent cases, for instance, of poisoning by gases, fumes, lysol, etc., drowning, electric shock and the always imminent risk of collapse in narcosis.

For a long period, however, mechanical assistance by means of the human hand has been the only form available in such cases. The hand is, naturally, soon tired, and, while in operation, introduces fresh air only very slowly into the lungs, so that success entails strenuous endeavor continued for hours. When, later on, the almost miraculous action of oxygen on the almost entirely stagnant lungs and heart began to be recognized, the desire for some improved method became all the more urgent, and we are now offered in the Pulmotor, an automatic resuscitation apparatus which renders the healing power of oxygen available in rescue work.

It produces the flow of the inhaled and the exhaled air by a single nozzle, the rhythm of respiration adjusting itself as automatically to the dimensions of the lungs and thus the astonishing result is produced that a seemingly lifeless body begins to breathe regularly, directly the Pulmotor is placed in connection with it.

*Paper presented at Ottawa Meeting, C. M. I.

Of course the apparatus cannot bring any person back from the dead, and no such claim is made for it; if, however, even the slightest trace of blood circulation, through the action of the heart, be present in the apparently lifeless body, the lungs are supplied with oxygen just as in natural respiration, so that the most favourable conditions imaginable for resuscitation are provided. The Pulmotor works directly on the respiratory organs and ,if the spark of life still exists, will fan it into flame and give the heart and lungs a chance to fight their own battle which they will do more valiantly than any mechanism that has ever been invented.

The whole of the apparatus is contained in a case weighing altogether 46 pounds, and is carried easily by one person. Besides the special apparatus for artificial respiration, housed in the case itself, it contains mounted on the lid of the case an oxygen inhalation apparatus for ordinary oxygen inhalation. The two apparatus have in common the oxygen cylinder, and the pressure reducing valve, and either of them can be set in operation simply by turnig a suitably arranged lever to the right or left. The oxygen cylinder is closed by a valve and as soon as this valve is opened, one or other of the apparatus begins to work. The cylinder contains 11½ cubic feet of oxygen and, when full, will keep the Pulmotor in operation for 40 minutes in succession.

The oxygen passes to an injector, which has the property of drawing in a large volume of air which it propels with equal force through the flexible tube in front of the injector, thus alternately filling the lungs by pressure and empting them by suction; the pressure is equivalent to 8-inches water gauge and the suction to 10 inches. Other important parts of the apparatus are the air reversing chamber and a small batter accordion bellows which effects the automatic reversal of the apparatus from suction to delivery and vice versa without ceasing, and which is perhaps the most striking invention of the Pulmotor. The operation of the bellows is extremely simple, it is connected with the air tubes and during inflation, the same pressure obtains in the bellows as in the lungs, but as soon as the latter are filled, the bellows becomes inflated and in moving forward causes the valve to be automatically reversed into position for suction. Then the operation is reversed and as soon as the lungs have been emptied the bellows contracts and automatically reverses the valves again into position for suction and so on. The great advantage is, as may readily be seen, that the respiratory rhythm of the apparatus really adapts itself absolutely automatically to the capacity of the lungs in every case, and that the apparatus performs all these functions, without any assistance being required from the hands. Consequently the whole attention of the operator may be directed to the patient and to the important tasks of keeping the windpipe open and of closing the gullet.

The keeping open of the windpipe is always the most difficult point in artificial respiration, this pipe being, in asphyxiated patients obstructed by the contracted and retracted tongue, and also by the epiglottis. The tongue should therefore be drawn forward in the proper manner, for which purpose a pair of forceps is provided in the case, before attaching the face mask covering mouth and nose of the patient, so as to ensure airtight connection between the Pulmotor tubes and the organs of respiration. The mask is secured to the face by two pairs of straps, which branch from a padded ring that is placed under the back of the head, so effecting a close fit all round.

It is further necessary to prevent any air or oxygen from entering into the gullet, i.e., the passage leading from the mouth to the stomach, as this would risk a distension of the stomach, if the apparatus is used for long at a time. The gullet is a flaccid, muscular tube, lying between the semi-rigid windpipe and the osseous spinal column. Consequently all that is necessary is the application of gentle pressure on the windpipe in the middle of the throat, which will compress the gullet against the spinal column in such a manner as to prevent the passage of air to the stomach, this pressure does not restrict the circulation of air in the semi-rigid windpipe. The accuracy of this reasoning has been proved beyond doubt through very interesting and subtle experiments with a surgical subject undertaken by Professor Dr. Roth, of Lubeck, Germany.

The inhalation apparatus attached to the lid of the case is intended for ordinary oxygen inhalation after artificial respiration has been successfully applied and the sufferer is again able to breathe naturally.

The success of the Pulmotor during the short period since it has been known, has been almost miraculous; it was first introduced to America by the Commonwealth Edison Co., in Chicago, who purchased the apparatus for the benefit of their employees in the frequent cases of electric shocks and at the same time put it at the disposal of the general public. According to their statement the Pulmotor has been called to resuscitate fifty-five persons overcome by poisonous gases in Chicago between January 16 and February 18, 1912. Of these forty-one were revived, four were dead before the apparatus arrived, four attempts at resuscitation were unsuccessful, and the others were not Pulmotor cases. The first call for the apparatus came on January 16. The patient had been overcome by illuminating gas, and when the operator reached the house with the Pulmotor there was just the faintest breath of life preceptible and the pulse was so feeble it could hardly be distinguished. No doctor could be reached and the operator went to work. The response was almost instantaneous and in half an hour the man was breathing naturally.

In another case a physician had already declared the patient dead and told the family there was no possible hope from any source when the Pulmotor arrived. In a few minutes, after the apparatus got to work, the pulse of the man showed great improvement and there were other encouraging signs. The doctor returned to the task, and a few hours later the patient recovered consciousness.

According to the statement of the above company the Pulmotor is practically infallible in cases of asphyxiation, drowning or any poisoning that produces sleep, and electric shocks, as long as there is still any action of the heart left.

The great usefulness of the Pulmotor for all those that work in mines or such establishments that necessitate the handling of chemicals, etc., is obvious, and a great number of mines in the States and in British Columbia are already equipped with Pulmotor.

The special Pullman car, which is used as a portable rescue station in American mining districts is also equipped with a Pulmotor, and it seems only a matter of time until the apparatus will be considered an indispensable part of any rescue station.

# EXTRACTS FROM REPORT OF S. PRICE, LIMITATION OF THE HOURS OF LABOR OF UNDERGROUND WORKMEN IN THE MINES OF ONTARIO

Dear Sir,—Pursuant to your instructions of August 10th, 1912, I have inquired into and considered the matter of legislation for the limitation of the hours of labour of underground workmen in the mines of Ontario and I now beg to make my report.

### Mode and Nature of Investigation.

My investigation has been for the most part informal. I have endeavoured by personal examination and by inquiry from the men and the mine managers to ascertain and understand the nature of underground employment in the mines, and the conditions under which the men work, and to gather what knowledge and information I could as to the effect which an eight hour law would be likely to have upon the mining industry. The fullest opportunity has been given for expression of the views of those chiefly concerned. Public meetings, advertised in the press and by posting up and distributing notices, were held in the most important mining centres and every one interested was invited to be present to make known his views, or to hand in or send me in writing anything he desired to say. The mine owners throughout the province have been communicated with and data collected from them regarding the number of men employed, the present hours of labour, the means of descent and ascent, the time taken for meals or rest and other matters which might have a bearing upon the question in hand. I personally visited a number of the mines in various parts of the province, spent considerable time underground seeing the men at work, and examining the character of their employment and the conditions surrounding it, and conversed with large numbers of the men and with their foremen and employers.

By these means and from petitions and letters, and other statements and material handed or sent to me by the men and the mine managers, by discussion with a large number of them, by taking a secret ballot from the men at a number of the mines, and by consultation with the mine inspectors and other officers of the province, and interviews with other disinterested persons having knowledge of mining affairs, I satisfied myself as fully as I could as to the views and wishes of both parties, and as to the facts and conditions having to do with the matter under inquiry.

I have obtained copies of and perused the eight hour laws in force in other countries, and collected what information I could get regarding their operation and effect.

The reports of Commissions elsewhere upon the eight hour question, and various articles and comment, opinions of political economists and other literature upon the subject, have also had consideration.

### Mine Workmen and Importance of Mining in Ontario.

About 7,700 men in all are employed in and about the mines at which there are underground workings (excluding smelters, concentrators and mills not operated in immediate connection with the mine). Of these 7,700 about 4,000 are underground men, who would be directly affected by the proposed legislation. These 4,000 underground men are distributed among the different mining districts of the province approximately as follows: Cobalt 1,800, Porcupine 440, Sudbury 1,000, Michipicoten 281, Elk Lake and Gowganda 74, Hastings and vicinity 154, Grand River district 57, various places in eastern Ontario 43, and in northwestern Ontario 124, the rest belonging to Swastika, Temagami and eastern Algoma.

There are no statistics as to the men's nationality, but the great majority of them are foreign born, especially in the Sudbury and Michipicoten districts, coming largely from Italy, Finland, Austria and Poland.

In most of the mines the greater number of the men are lodged and boarded by the mining company, being either unmarried or having a family living elsewhere.

The total annual wage list for these mines is over $6,000,000, and if the smelters, concentrators and mills in the province were all included this would add some three or four million dollars more.

It need hardly be pointed out that by reason of this large wage bill and by reason of the great quantity of provisions, machinery and supplies of various kinds used in and about the mines, the province generally reaps great advantage from its mining industry. The enviable position which Ontario now occupies as easily the premier mining province of the Dominion, and one of the great mining districts of the world, is not only a matter to be proud of, but is something that brings substantial benefit to a large part of our population. The farmer, the merchant, the manufacturer, the railway man and many others of various occupations reap advantage from the prosperity of this industry, and all are interested in its welfare.

### Present Hours and Conditions.

The present hours of labour underground vary from 8 to 10 hours, mines which are side by side often differing. Of the 86 mines from which complete returns have been received 40 work 10 hours a day, 32 work 9 hours, 10 work 8 hours, 2 between 8½ and 9 hours and one works 9½ hours. The average for the province would be a little over 9 hours. A number of what are called prospects, not included in the above, work more or less irregularly.

The depth of the mines varies all the way to 1,300 or 1,400 feet, but the great majority of the workings are less than 400 feet and very many of them less than 200 feet deep. In 46 of the mines the means of descent and ascent is by ladder, in 24 by lowering and hoisting of cage, in 13 both means are used, and in 4 entrance is by tunnel or adit. The number of mines using the cage is increasing, but for depths not exceeding 200 feet the ladder seems preferable by reason of being safer, though the men as a rule no doubt generally prefer the cage.

Nearly all the mines in the chief mining districts work two shifts a day—a day and a night shift, each commencing at 7 o'clock morning or evening a sthe case may be and quitting at 6, 5, 4 or 3.30, an hour or less being usually taken for dinner or lunch about the middle of the period. When shafts are being sunk or other work is desired to be specially rushed three shifts a day of 8 hours each are usually put on. It might also be mentioned that for shaft-sinking or other very wet work extra pay is generally allowed. Often the hours are shortened or changed on Saturdays by reason of Sunday intervening or to give a part holiday.

### What the Men Say.

Careful inquiry and test by ballot, where that was considered desirable, satisfies me beyond doubt that the men, under whatever system of pay they are working, are nearly all in favour of an eight hour law. The meetings held at Porcupine and Cobalt which were largely attended, and those at Sudbury, Marmora, Kingston, and elsewhere, at which the attendance was slight, expressed themselves unanimously, so far as the men were concerned, in favour of the eight hour legislation, and this after the matter had been explained and discussed and after the mine manager's statement declaring that it would involve a deduction in pay, had been read to them. Petitions purporting to be signed by a number of men at Elk Lake (not all, however, miners), and by nearly all the underground men of two of the important mines at Sudbury, and resolutions and addresses from the miners' unions, asking and arguing for the law, were presented to me. Owing, however, to statements from the mine managers that many of the men were really not in favour of the eight hour law, but against it, but that they sometimes did not like to say so, I determined to test the matter by distributing a ballot by which the men could express their wishes secretly if they desired. Care was taken to include a number of the mines as to which I was satisfied the relations generally between the owners and the men were good. In nearly all the mines where the ballot was taken I am satisfied that the men as a rule are well treated and not at all dissatisfied in general with the way they are used by their employers. In a number of cases I know a good deal of pains have been taken by the employers to look after the men's welfare. The result of the ballot, however, was to show that even in these cases and in cases where the men did not belong to any miners' organization nearly all the men desired the eight hour law, 332 ballots being returned in favour of it and only 12 against it. Six of the ballots marked for it, however, had the words "with a minimum wage" written upon them, and 3 of those marked against it asked for a 9 hour day. The most significant feature in regard to this ballot was the fact that where the men are paid by the piece and depend for the amount of their pay on the amount of work they can do in a day they are almost as strongly for the law as in the places where the pay is by the day, and before the vote was taken the difference in their position as compared with other places and the effect the proposed law would have in reducing their pay, unless they could do as much work in eight hours as they are now doing in ten, was carefully pointed out and explained to them. As expressed at some of the meetings, the feeling of the men seemed to be "get the law passed anyway and see about the matter of pay afterwards."

The chief grounds urged are as follows: First, the humanitarian aspect — that working underground is working under unnatural and trying conditions, being away from the surface and the sunlight and in air more or less impure and inferior to the natural air, being often contaminated with fumes of gas and with injurious dust or particles from the drilling and other operations. They complain at Cobalt that the hydraulic air used in a large number of the mines there is not as good as the air of the ordinary compressor. It is a frequent occurrence they say in underground mines to have men overcome by gas from the blasting powder and sometimes to lose their lives thereby, and they say headache and sickness from the powder are common. They say that the work is dangerous and a strain on the system, and that the working places are often wet or damp and the work usually strenuous and more exhausting and harder on the constitution than similar work would be on the surface, and that the mining life of an underground miner is short. They claim that eight hours efficient work is all the ordinary man is capable of, and that exhaustion or dulling of faculties causes accidents to be more frequent in the latter part of a long shift. They point to the various other mining countries where the eight hour law is in force, and ask why Ontario should not be as good as these. Some say that a better and more efficient class of men would be induced to come into Ontario if the hours of labour were as favourable as in British Columbia and the Western States. Many say that those who oppose reduction of hours think only of dividends and are willing to sacrifice the health of the men for money.

Most of the men also claim that with proper system and management as much work can be done in eight hours as is now done in nine or ten, and that there would be no decrease in the output of the mines or increase in the cost of production. There will always, they say, be objections made to any change in existing conditions, and they claim that the cries of injury to the industry raised in other places when the law was being put in force there have proved ill-founded.

They urge that the eight hour law should apply to all mines, with no qualification or exemption, except only for cases of emergency where life or property is in imminent danger, and that it would be fatal to the usefulness of the law to exempt contract or piece work or to complicate the Act by special provisions or exemptions.

### What the Mine Managers Say.

The mine managers generally oppose the eight hour law. Less than half a dozen are wholly in favour of it, a few are not strong one way or the other, while others would not object to it if it was made eight hours face to face and not bank to bank and provisions were inserted to meet special conditions and contingencies. Quite a number would have no objection to a nine hour day.

The arguments urged against the adoption of the eight hour legislation are very numerous, but those in which the greater number of its opponents concur are: That it would mean reduction of wages and consequent dissatisfaction of the men; that it would decrease the output and profits of the industry, make low grade propositions unworkable and discourage influx of capital; that the eight hour law has in fact had disastrous effects in British Columbia, Australia, and parts of the United States, and is driving capital and labour out of England and the United States; that the popular belief that underground employment on the present basis is injurious or objectionable is not correct, experience, the hospital records, and the fact that men prefer underground to surface work being appealed to in support of this contention; that legislation upon such a question is not wise, and that it would be inexpedient to disturb existing conditions, which it is claimed are generally satisfactory to the men who are willing to work.

It is also urged that by a large number that, even if such a law were proper or desirable in very large mines or in more advanced stages of the industry, it is not justified in Ontario, where most of the mines are comparatively small and the industry largely in the development stage; and it is pointed out that while some of the mines pay very large dividends many others in different parts of the province have but a slight margin of profit and cannot bear increased expense.

By the Cobalt mine managers it is also urged that they have to compete in silver with Mexico, which has cheaper labour and less expense by reason of a warmer climate; that they have to pay supplementary revenue taxes and some of them royalties, and that freight and other charges are high; that a shorter day would necessitate greater speed and conduce to increase of accidents; that as the time of actual operation of the drills is only 6.45 hours a day, the rest of the 10-hour day being taken up in going to and from work, taking down and setting up drills, blasting, etc., a reduction of two hours in the working day would mean only 4.45 hours of actual drilling, and would therefore cause a reduction of 31 per cent. in the output and in the dividends.

### Operation and Effect of Eight Hour Laws.

In addition to what information I could glean from articles and reports and from interviews with persons having more or less knowledge of conditions in places where eight hour laws are in force, a number of the mine inspectors of British Columbia and of the Western States have been good enough to answer a list of questions which I submitted to them regarding the operation and effect of the law in their country, and to give me their opinion generally as to the expediency of such a law.

Chief Inspector Graham, of British Columbia, where the eight hour law has been for a long time in force, thinks it increased the cost of mining slightly, but very slightly, but that it does not decrease the output, though it may mean a reorganization of the working forces. He says the men unanimously and the operators generally favour its existence, and that instead of being injurious it is beneficial to the mining industry. He is decidedly in favour of having such a law. Inspector Strachan, of the Nicola Valley district, gives answers generally much to the same effect, but thinks the law does not increase the cost of operating, and believes the eight hour day is better for the company financially, and he says he has found none of the operators now desiring to have the day longer than eight hours, and he is even more strongly in favour of the eight hour law than the Chief Inspector. The inspector of the West Kootenay district thinks the eight hour law does decrease the output, but does not think it is injurious to mining industries, and thinks an eight hour law in mining is desirable.

Mr. Henahen, Commissioner of Mines, Colorado, where the eight hour law has been in force since 1904, thinks the law does not raise the cost of operating and that such a law is desirable in mining. He says the workmen favour it, and that the metalliferous mine operators generally favour it also. Mr. Bartholomew, Secretary of the Bureau of Mines, Missouri, which has had the eight hour law since 1899, is not prepared to answer as to the effect of the law on the output, but says the men and the operators generally favour its existence, and that he thinks it is desirable to have such a law. Inspector Walsh, of Montana, where the eight hour law came into force in 1907, does not think it raises the cost of operating and says that the men, and in most cases the operators, favour its existence, and his opinion is that the law is desirable in mining. Inspetcor Jones, of Wyoming, says the eight hour law raises the cost of operating at first, but thinks, with proper adjustments to meet the altered conditions, this can be more than offset. He says the men favour its existence, but that the operators are not favourable to outside regulation. He thinks the law is desirable. State Inspector Bell, of Idaho, thinks the eight hour law raises the cost of operating proportionately and decreases the output of the mine, but the men and most of the operators favour its existence, and he thinks such a law is desirable in mining. State Mineralogist Storms, of California, where the eight hour law has been in force since 1909, thinks it raises the operating tonnage cost and undoubtedly decreases the output. He says the men generally favour its existence, but some of the operators are opposed to it. He thinks, generally speaking, such a law is desirable in mining.

Mr. Sutherland (now Assistant Inspector of Mines in Ontario), who has had extensive practical experience in a number of the mining districts of the west, says the men and he thinks, generally, the operators favour the existence of the eight hour law where it is in force, and he thinks it does not decrease the output of the mines and that it is not injurious to the mining industry.

As to the operation and effect of the eight hour law in England, where it went into force in 1909 and 1910, all the information I have obtained has been derived from the inspectors' official reports and from information which Sir George Askwith, of the Industrial Commissioner's Department, has been kind enough to give me. It seems that owing to the customs and privileges which had grown up in different parts of the country some friction occurred at first as to a number of matters, but the law seems now to be working pretty smoothly. The comparatively short time it has been in force and the other labour disturbances that have occurred and the changes that have been made in other respects make it difficult to tell what are its effects. It does not appear to have decreased the output, but the chief inspector, while thinking there has been an increase in the working cost per ton, says it is impossible to say how far this is due to the operation of the "Eight Hours" Act. On the whole it would not appear that any very material economic effects are attributed to the operation of the law.

### Independent Opinion in Ontario.

I have discussed the question of an eight hour law very fully with our own mine inspectors and other officials and with other disinterested persons familiar with mining conditions. The inspectors, whose efficiency and usefulness I found in my visits to the mines to be held in high respect both by the operators and the men, naturally and properly do not wish unduly to take part in any controversy between the two parties, but their knowledge and experience in these matters and the opportunities they have had for understanding circumstances and conditions are such that it seemed to me imperative to obtain the benefit of their knowledge and that I have consulted them; some of the information they have given me upon these is more particularly referred to in other parts of the report, but I think it is right to say here that they and the other mining officials with whom I have discusesd the eight hour day do not seem to fear evil results from it, and Inspector Sutherland is very strong in the belief that a reasonable eight hour law for underground workers would be beneficial.

I think the weight of well-informed independent opinion is in favour of the law.

### Review of the Matter.

From what has already been stated I think it must be concluded that foreboding of disastrous results to the mining industry if an eight hour bill is enacted are not justified. The mine managers do not produce any figures or evidence in support of their prediction that injury would result, except statements of a number of mining men who attribute their financial difficulties in whole or in part to the eight hour law, and a reference to the closing down of a number of mines in British Columbia after the eight hour bill went into effect. Other opinions, however, do not attribute these things to the reduction of the hours of labour. Inspector Sutherland and others think the trouble in British Columbia was due to other causes, and it may be pointed out that returns indicate that the past year's mining operations in British Columbia have been the most profitable in the history of the province. The strongest support I have found in favour of the contention that the mining industry would be injured is the refusal of the Commission on Hours of Labour in Nova Scotia in 1910, to recommend the eight hour day for the coal miners because they believed such a law would undoubtedly add to the cost of operating or seriously reduce wages, and because apparently they feared injury would in consequence result to the coal industry, which as they pointed out had to meet competition from other places.

In the British coal mines the average hours of labour prior to the enactment of the eight hour law were about the same as we now have in Ontario, and the Commission dealt pretty fully with the matter of reduction of output which the owners claimed wolud result, and arrived at the conclusion that this would not be so great as claimed though they believed some diminution of production would follow. The actual effects, as already pointed out, seem at least no worse than the Commission anticipated.

With regard to the figures as to drill time submitted by the Cobalt Mine Managers, and the contention based thereon, which is very similar to what was urged by the coal mine operators in Great Britain, I am told by independent persons having knowledge of these matters that there is no reason why the actual drill time should not be a good deal longer than the contention indicates. I am informed also that it is claimed by the managers of the mines in Ontario which are working on an eight or a nine hour basis that their costs are as low as those of ten hour mines, and western shiftbosses and mine captains working in the Ontario mines claim that they can get as much work done in eight hours as in ten. It is stated and admitted on nearly all sides that the amount of work done generally in the Ontario mines is not satisfactory for the time that is spent at it, and that in fact the efficiency of a great many of the men is not as high as it should be.

What the effect of the enactment of an eight hour law would really be on one of course can definitely say. As pointed out in the report of the Miners' Eight Hour Day Committee in Great Britain in 1907, much would likely depend on the spirit in which the law was received and the efforts made to adapt operations to the new conditions, and to minimize friction between the men and the employers. Probably upon the whole the conclusion that would be most warranted is that while results might vary in different places or under different circumstances and while there might probably, generally speaking, be some increase in cost of production, the increase which may reasonably be feared is slight.

The fact that little or no injury would likely result to the industry or that the mine owners are able to stand a diminution of profits is no ground for a change or disturbance of conditions unless other reasons warrant or require it. Neither on the other hand I think would even material decrease in output and profits be reason for refusing the law if the conditions in regard to the health and welfare of the workers were so serious as imperatively to require it.

Turing to the latter question, I am convinced that the popular idea of hardship and injuriousness of working underground is only partly right. The mines of Ontario, I believe, as a whole, are naturally as healthful as any in the world. Figures and opinions show that there is little in the assertions regarding arsenic poisoning in the Cobalt mines, though, no doubt, through infection, that does in a few instances occur. There seems, however, to be better basis for the fear of harm arising from the breathing of the dust caused by the drilling and other operations, and especially from the hammer drills where no water is used to allay the dust, and particularly in the quartz workings. Phthisis or miners' consumption is at present a disease little known in Ontario, but the time has been short for its development and it is undoubtedly a matter to be considered and as far as possible guarded against. Our inspectors are fully alive to this necessity and no doubt will do their best to minimize the evil, but I may here mention that one of their difficulties is that the men are not always as willing as they should be to co-operate in precautionary measures. It is undoubtedly true that there is a good deal of powder gas in many of our mines and that this causes considerable trouble, and is more or less harmful even where the men are not actually overcome by it and no fatality occurs thereby. I think it cannot be questioned either that underground mining though not the most hazardous of occupations, must be distinctly classed as a hazardous one. The allegation of greater frequency of accidents in the latter hours of shifts I find after very careful investigation, assisted by the hospital records and other figures produced by the managers, and especially by the data put together for me by Chief Inspector Corkill, is not borne out by the facts. The figures really show that a rather larger percentage of the accidents take place during the early hours of the shift than during the later hours. Reports and opinions do not on the other hand confirm the allegation that shorter hours and consequent speeding up would be likely to increase accidents. Hospital records do not show a large percentage of sickness among the miners. The Commissioners in the British eight hour day report already mentioned, find that the health and physique of coal miners in Great Britain compares favourably with that of other work people, although the eight hour law was in fact adopted there. The best information I have been able to get shows metalliferous mines as a class to be generally less healthful than coal mines.

The prevailing view expressed in the reports received from the inspectors and other officials of British Columbia and the Western States, is that in their opinion underground work is more injurious to the health than surface work, and that there are special reasons why underground men should have shorter hours than other workmen. The eight hour mining laws, as a rule at least, seem to be based upon that assumption, some of the United States statutes specifically so declaring. I am not unmindful in considering the above reports that officials will naturally be disposed to favour their own law, and that the employers whose opinions they refer to in support of the law may not feel disposed to complain of what they cannot help; nor do I forget that the exigency of the situation in the United States from a constitutional point of view may have something to do with the legislative declarations as to the injuriousness and danger of underground employment. Neither do I neglect what is said by the mine managers here, which I think is to a great extent true, that men after getting used to working underground prefer that to surface work; but higher wages and a certain fascination about it, and a sense of pride o rdignity in having attained to a higher or more important stage in the mining occupation, probably account largely for the preference. Whatever the reason may be such a preference is not incompatible with the statement that the occupation is in fact unhealthful and injurious.

Undoubtedly the air in mines even under favourable conditions is not as good as ordinary air. It contains a smaller percentage of oxygen (especially where hydraulic air is used), is more or less laden with dust or small particles of rock or mineral and with powder gas—the prevalence of which, however, varies very greatly in different cases—and as natural ventilation is always poor other impurities also are pretty sure to be present. There is besides usually more or less water or dampness underground, though our inspectors say that as a class the Ontario mines would be considered dry in comparison with others. Working under these conditions, and always by artificial light, I think cannot reasonably be contended to be as good for the worker as working under ordinary conditions, and the element of danger may add something to the burden. It is estimated that 80 per cent. of the underground men are under 40 years of age and 90 per cent. under 50.

Upon consideration of everything I have been able to gather I think the conclusion must be that working underground is unhealthful and injurious, though not at all to as great an extent as is claimed by a number of the men or as is ordinarily believed by persons unfamiliar with mining conditions.

Some of the statements put forward as arguments for or against the law are not relevant. That the workmen have among them persons who favour the law upon grounds that do not commend themselves to the general community, or that they have in their ranks or in the organization to which a number of them belong, individuals who are not a credit to them, should not condemn their case if it is in fact meritorious; though I think the importance to any body of men of so controlling their members as to maintain public opinion upon their side can hardly be over-estimated. I should be sorry on the other hand to see any law put in force for no better reason than that those upon whom it may be assumed to be a burden are making large profits and are well able to bear it, even where that is the case. The prevailing idea, however, that the mine owner gets his money easily is far from being always correct. While some of the mines may return investment a hundred fold and be almost able to pay their last year's wagebill from the mere advance in the price of their product, there are many where profits are very much smaller, and some where more money goes in than ever comes out. I have sometimes felt that the mine owners of Ontario have not always had the sympathy that they should have from the rest of the population, but objections on the ground of taxation and royalties, which have no relevancy in the present inquiry and which can only be regarded as complaints against what the people of the province generally regard as just and reasonable, can hardly be hoped to enlist public opinion in their faour. But this is beside the question.

A consideration which I think should have weight is the tendency the proposed legislation would likely have toward allaying unrest and removing friction and difficulty existing in a number of the mining camps. Taking out of the field of controversy and settling permanently what has been and will apparently likely otherwise continue to be a fruitful source of trouble between the employers and the men would of itself be a good deal gained. Sir George Askwith, speaking of the question generally, and Inspector Sutherland, speaking of conditions in Ontario particularly, are both of opinion that the eight hour day will likely come sooner or later, or will be a source of agitation until it is obtained, and they both see advantages in establishing it now. The history of the matter in Ontario supports this view. There has been a gradual reduction in the length of the day in a number of the mining districts. The newer camp at Porcupine has, on the whole, considerably shorter hours than Cobalt, and lately the shorter day has been introduced in some of the mines in the older districts. As already mentioned, it is not only the miners' organizations that are wanting the shorter day, but also the men who neither belong to the union nor live in districts where unions exist, and those working by piece work or contract, as well as those working for day wages. This desire of the men for the law, I think, is an important consideration in estimating its desirability. It cannot, of course, be hoped that the legislation would settle all difficulties and wholly prevent strikes, but it would remove one of the chief causes of trouble.

I think there is something, too, in the contention that the shorter day would tend to greater skill and efficiency of the men, and that by improving conditions it would encourage a more permanent class of residents in the mining camps and lessen the very large remittances of wages now sent out of the country by those having no established home here.

### Recommendations.

Everything considered, I think the balance is in favour of enacting a reasonable eight hour law for underground workmen in the mines of Ontario.

Of the laws in force in other places, I think that in Great Britain is the most carefully devised, and that its principles should, in the main, be followed, with simplification of some of its provisions where that is possible.

Subject to proper safeguards for securing suitable means of descent and ascent, I would recommend that the law respecting metalliferous mines in British Columbia, and that in force in most of the Western United States, approximating closely in this respect to the laws of Great Britain and France, should be followed as to mkaing the eight hours from face to face rather from bank to bank.

The law, I think, should apply to contract and piece work, as well as work by the day, and men as well as employers should be obliged to observe it, notwithstanding any consent or agreement between them; otherwise I think the chief benefit of the law would be lost.

I think no overtime or deviation from the Act should be permitted except in emergencies where life or property is in danger and for repair work and an exception for Saturdays; but I think pumpmen and shiftbosses and persons engaged solely in surveying or measuring might properly be excepted from its provisions, and I think, having in view the conditions now prevailing at a number of the mines, the time taken for dinner or lunch, not exceeding half or at most three-quarters of an hour, should be excluded, and I do not think the usefulness of the Act would be materially impaired by exempting workings where not more than six men are employed in a shift. Very strong representations have been made to me in respect of the hardship an inelastic eight hour law might entail in performance of development work, especially in out of the way districts, and I think this exemption might safely be conceded.

I would suggest that the mine managers, in order to be permitted to exclude the time taken in descending and ascending, should be required to obtain from the mine inspector a certificate that the means provided for descent and ascent are satisfactory. I think also the question as to whether a shift is in fact composed of not more than six men should, in case of dispute, be determined by the mine inspector.

In answer to a question asked, I would say I do not think it would be desirable that, instead of enacting a positive eight hour law, the fixing of the hours of labour should be left with a Board. That, I think, would be sure to cause trouble, and would destroy one of the chief benefits I see in passing the legislation.

I can see no harm in inserting a provision such as the British and Alberta Acts contain, empowering suspension of the law by Order-in-Council in the event of great emergency or grave economic disturbance.

The provision in the British Act allowing an extra hour during periods not exceeding 60 days in the year is, I think, unnecessary here, and would only tend to cause complication.

Following the course pursued in the enactment of similar laws in a number of other places, I think, in order to permit of preparation for it, the coming into effect of the Act should be postponed for a reasonable time—not less than six months—from its passing, and, perhaps, it would be but fair to postpone it longer in respect of the mines or the district where there have recently been strikes, as it might be considered a hardship upon the mines which, according to the findings of the Arbitration Board, have not been in the wrong, to disturb conditions again after so short an interval.

Faithfully submitted,

S. PRICE.

St. Thomas, Ont., January 27, 1913.

# PRINCIPLES ON MINE VALUATION.*

By James R. Finlay.

Almost all enterprise is based on valuation of some kind. Practically all transactions in mining property, whether it be in stocks, bonds, or actual ownership, are based on some kind of an appraisal of values. If you expect to be employers instead of employees you should begin at once to study the factors which give value to things. You can not buy intelligently nor sell intelligently until you know how to form an estimate of what a given property is worth to you, to the man you are dealing with, and to anyone else who might be brought in. It is only by such knowledge that one can discern a bargain or avoid a disastrous venture.

This generalization has no more application to mining than to any other form of business; but it certainly does not apply to mining less than to other forms of business. I think that no more unfortunate idea is taught to young mining engineers than that they are to consider themselves merely as professional men, like doctors or ministers. I would not speak of this if such an idea had not been cultivated in certain quarters. It is true that some mining engineers are employed to do technical work as referees between conflicting interests. Professional honesty is of course an absolute essential, but the honesty of a mining engineer is the honesty of business and of common sense. It is not in the least desirable for a mining engineer to avoid business transactions; on the contrary he should go into them as soon as possible and study the subject in every possible way. I do not see how any man can make a success of mining who does not realize that it is a strictly commercial business; that the only result to be sought is commercial success; that the only scientific and technical attainments that are worth anything are those which contribute to commercial success. Attainments of a different character are, of course, worth while; but they are valuable to a mining engineer because he is a man and a citizen, not because he is a mining engineer. They would be equally valuable in every kind of profession. Success in business is measured in money. Technical skill is efficient only if it pays. One can judge of the value of technical excellence only if he is prepared with a knowledge of what constitutes the money value of the results of such technical excellence.

Undoubtedly this view of the mining business, or pro fession, has been gaining ground in our universities and technical schools. Formerly, I think, education was considered to be merely a training in principles. Technical training was a discipline in the science of action (I coin the expression), an exposition of the principles of doing things. Whether it was worth while, in dollars and cents, to do a thing was to be found out later in actual business. Now I think it is recognized that, while making money is of course a matter of actual occupation in business, there are certain general principles underlying the value of things, which are well worth study. This is the study of political economy, which is largely taught in all our universities. The mining engineer sooner or later comes into contact with this subject and is bound to find it interesting and important. I shall try now to advance a few ideas about the valuation of mines, which I think are basic enough to come under the head of general principles.

The first thing to which I wish to draw your attention is the general subject of valuation. What is it that causes a price to be fixed for commodities or properties? In general, there are two methods of fixing values; one is the empirical method, and the other, the constructive. The empirical method of fixing values is simply to obtain a record of facts—of transactions. A man will assume that a town lot is worth $100 because he finds that people have bought and sold similar lots for $100 apiece. Nearly all commodities of a retail nature are valued in that way, and it is perfectly logical that they should be, because each actual transfer is a bargain between the buyer and the seller, the-

*A lecture in the Department of Mining, Columbia University, December 2nd, 1912.

oretically at least. The man who sells for a certain price does so because he believes he can do it profitably. On the other hand, the man who buys figures the same way from his side. Consequently we find that wheat, iron and copper, as commodities, are valued empirically by merely ascertaining what sales are made; and fluctuations of price are established by supply and demand. If a commodity is anxiously sought for by more people than can be supplied, they bid up the price.

The constructive method is that which places the value of commodities in a more or less scientific manner—builds up logically an estimate of what it properly should be worth. This naturally applies to properties which are dealt in only occasionally, for which there is no precedent of an actual sale of the equivalent thing. You will easily see that mines belong to that class of property.

Hardly any two mines are exactly alike; therefore you cannot say logically that because one mine is worth one million dollars, another mine is also worth one million dollars—at least you cannot say so until you have gone through the factors which give both properties value, and have found that they are identical. It is to those factors which do give values to mines that I wish to call your attention now.

(To be continued)

# PERSONAL AND GENERAL

Mr. Alex. H. Smith, of Carter & Smith, has quite recovered from the painful accident that he suffered some weeks ago in Porcupine, and has left for Arizona, after completing several examinations in Eastern Ontario.

Mr. Geo. H. Aylard, now of Victoria, B.C., under whose supervision the Standard silver-lead mine, in Four-mile camp, Slocan Lake district, was developed from a mere prospect to an important ore producer, is spending a few weeks at Silverton and New Denver, within a few miles of the Standard.

Mr. G. O. Buchanan, of Kaslo, B.C., Dominion Supervisor of Lead Bounties, has lately been fully occupied getting in returns of lead mined and smelted in British Columbia, to the close of the fiscal year ended March 31.

Mr. W. A. Carlyle, who in the nineties was actively associated with mining in British Columbia following several years as Professor of Mining and Metallurgy at McGill University, and later was general manager of the Rio Tinto copper mines, in Spain, has resigned the professorship of metallurgy in the Royal School of Mines, London. His resignation is to take effect in June, after which he will resume practice as a consulting engineer, entering into partnership with Mr. John F. Allan, a well-known consulting engineer who, beside important consulting connections, has been in the service at different periods in a managerial capacity, of the Rio Tinto Co., Mexican G. and S. Recovery Co., and Caucasus Copper Co., respectively.

Mr. A. B. Clabon, of Vancouver, B.C., who with Mr. Fred M. Wells has been actively associated during the last year or more with the development of the property on Princess Royal Island of the Surf Inlet Gold Mines Co., is arranging for a resumption of work on the Kingston property, in Hedley camp, Similkameen.

Mr. W. B. Dornberg, of Spokane, Washington, manager for the Treasure Mountain Silver-Lead Co., (which is developing a promising silver-lead property situated in Tulameen district and is distant from Otter Flat, B.C., about 20 miles), has been spending a week in Victoria.

Mr. Howard W. DuBois, of Philadelphia, Penn., managing director of the Quesnelle Hydraulic Gold Mining Co., is making preparations for the ensuing gravel washing season's hydrauliking operations at the company's placer gold mine in Quesnel mining division, Cariboo district, B.C. Mr. DuBois gave the annual meeting of the Canadian Mining Institute at Ottawa last March an interesting account of what his company had done in Cariboo, and showed a number of lantern slides illustrative of its work.

Mr. S. S. Fowler, of Riondel, Kootenay Lake, B.C., general manager for the New Canadian Metal Co., operating the Bluebell lead mine, the first lode mine discovered in British Columbia, spent several days at Victoria about the middle of April.

Mr. Hamilton, for some time in charge of the Cerre de Pasco Mining Co.'s reduction works at La Fundicion, near Tinhauarca, Junin, Peru, has succeeded Mr. A. B. W. Hodges as general manager for the company. La Fundicion will still be his headquarters.

Mr. Lionel Hill, assistant to the manager of the mines of the le Roi No. 2, Ltd., at Rossland, has left British Columbia on a three months' trip to England.

Mr. C. Hankel, formerly with the Zinc Corporation, who for about a year had been advising Mr. M. S. Davys, managing director of the Silverton Mines, Ltd., in connection with the designing of a concentrating plant to treat silver-zinc ore, from that company's Hewitt-Lorna Doone mines, in Silverton camp, near Slocan Lake, and the erection and equipment of a concentrating mill, has left British Columbia on his return to England.

Mr. John Hopp is back in British Columbia from a business trip to Eastern Canadian and United States cities. As the hydraulicking season is approaching, he will shortly prepare for operating. The snowfall having been heavy during the 1912-1913 winter, a long and profitable gravel washing run is expected this year. Mr. Hopp has four or five hydraulic placer-gold mines, situated within a few miles of Barkerville, Carbioo district, including leases on the famous Williams creek and on tributaries of the equally well-known Lightning Creek.

Mr. P. F .Horton, superintendent of the H. B. mine on Deer Creek, near Salmo, Nelson mining division of British Columbia, has been spending a month in Victoria and other coast cities. With the breaking up of the snow road and the unsuitable conditions for heavy hauling in early spring, shipment of ore has had to be temporarily suspended, but as soon as the wagon road shall be hard enough freighting will be resumed. The output capacity of the H. B., which ships lead ore to Trail, is now about 1,000 tons a month.

Mr. H. M. Lancaster, who ten to twelve years ago was engaged in mining engineering work in Rossland camp, and who since 1903 has been connected with mining in the states of Idaho, Montana and Washington, has returned to Rossland with the intention of again giving his attention to mining in British Columbia.

Captain J. Edwards Leckie, formerly of Cobalt, but now of Vancouver, B.C., recently gave an address on "Cobalt and Northern Ontario" before the local Chamber of Mines.

Mr. Duncan McIntosh, of Greenwood, Boundary district, B.C., long connected with the development of mining properties in that district, has been in Vancouver and Victoria for several weeks.

Mr. Robert McKee, after whom McKee Creek, in Atlin camp, was named, was reported in coast newspapers to have been in Seattle early in April with about $400 worth of placer gold from the Silver Creek diggings, situated in the northeastern part of Atlin mining division. Many placer claims have been staked on Silver and other creeks south of Teslin Lake, during the winter, and much work will be done this spring to test the value of the new diggings.

Mr. J. L. Parker, formerly manager of the Pacific Metal Mines Co., of Vancouver, B.C., is now manager of a coal mine near Diamond City, near Lethbridge, Alberta.

Mr. and Mrs. Bedford McNeil will be the guests of Mr. J. B. Tyrrell during the Toronto meeting of the International Geological Congress. Mr. McNeil is president of the Institution of Mining and Metallurgy.

Mr. Hallett R. Robbins, at one time engaged in development work on a group of mineral claims situated in Hedley camp, Similkameen, British Columbia, and afterward practising as a mining engineer, with office in Seattle, Washington, is now assistant professor of metallurgy at the State College of Washington, Pullman, Wash., in succession to the late Mr. Roswell E. Sampson, who was killed by a railway train.

Mr. T. A. Rickard, of London, editor of The Mining Magazine, has been elected a corresponding member of The Canadian Mining Institute.

Mr. J. M. Ruffner, manager of the North Columbia Gold Mining Co., which is the largest operator of hydraulic placer-gold mines in Atlin camp, British Columbia, has returned to that province after having spent the latter part of the winter at his home in Cincinatti, Ohio.

Mr. W. J. Watson, of Ladysmith, Vancouver Island, B.C., manager for the Tyee Copper Co., has gone to England to confer with the directors of the company relative to a possible sale of the Tyee smelting works at Ladysmith, there not being at present a sufficiently large supply of custom ore obtainable to make it probable the company will soon be in a position to resume smelting operations at the works.

Mr. E. H. Webster, assistant manager for the Motherlode Sheep Creek Mining Co., operating a gold mine and 10-stamp mill in Sheep Creek camp, Nelson mining division, B.C., has resigned that position to return to Los Angeles, California.

Mr. Fred M. Wells returned to Vancouver, B.C., on April 14 from Surf Inlet, Princess Royal Island, where he had been developing a gold mine.

Mr. Walter A. Bell, of St. Thomas, has won the Dana Fellowship in geology at Yale University. Mr. Bell is a graduate of Queen's University, where he studied under Professor M. B. Baker.

Mr. S. N. Graham, manager of Peterson Lake mine, recently visited Kingston, Ont.

Mr. Charles Heys, of Thos. Heys and Sons, has returned from a long visit to Nicaragua.

Mr. George R. Rogers, manager of the Mann mine, Gowganda, has returned to the mine after spending some time in Toronto.

Dr. A. Strachan, accompanied by Mrs. Strachan, will attend the meetings of the International Geological Congress as official representative of the British Government. Dr. Strachan is Assistant-Director of the Geological Survey of Great Britain.

# SPECIAL CORRESPONDENCE

## NOVA SCOTIA

### ST. LAWRENCE NAVIGATION.

The opening of navigation for St. Lawrence ports will be unusually early this year. Up to the fifteenth of April the Dominion Coal Company had sent three steamers with coal to Quebec, and shipments should continue regularly from this on. This is at least three weeks earlier than the first shipments in 1912, and the lead gained should be of great assistance in sending the necessary quantity of coal to St. Lawrence ports during the coming summer. It may be confidently expected that shipments up the river during the ensuing season will be greater than in any previous season. The mines have worked without interruption throughout the winter months, and the stockpiles are unusually heavy.

Some recent remarks of Prof. Barnes, of McGill University, have set people thinking as to whether all is being done that it is possible to do to lengthen the period of open navigation in the St. Lawrence River. The question is one which interests the coal trade of Cape Breton more than any other single industry, as probably the greatest problem at the Cape Breton mines is to equalize summer and winter conditions. Prof. Barnes states his belief that a proper service of ice-breakers, such as are used in the Baltic, could keep open a passage from Anticosti to Quebec during the greater portion of the winter, and that with the provision of anchorages for use at night and in snowstorms it would be possible to send vessels to Quebec from the ocean all through the winter. It is certain that in the winter just passed navigation to Quebec was possible until some time in January. The real hindrance to Cape Breton shipping comes in the drift ice season, which covers the months of March and April, and in late springs, even the month of May. The thickness and compactness of the drift icefields varies with the prevailing winds, and sometimes the icefields blockade the Newfoundland shore, and sometimes the Cape

Breton shore. Until the icefields commence to come down from the north there is no hindrance to shipping from Cape Breton ports except the inclemency of the weather and the storms of winter, and it must be said that these are not allowed to interfere very much with business in Cape Breton. If it were possible to bring about the conditions which Prof. Barnes thinks are not impossible then it would enable the Cape Breton mines to ship coal to Quebec all the year round, with the exception of the drift ice period. It must, of course, be borne in mind that the winter of 1912-1913 was a phenomenal one in many respects, and that the temperature in the River St. Lawrence falls extremely low in January and February. Long continued and blinding snow storms have also to be reckoned with.

### DOMINION COAL OUTPUTS.

The output of the Glace Bay mines for March was 370,916 tons, making a total for the first quarter of 1,092,196 tons, compared with 964,525 tons for the first quarter of 1912. The Springhill production was 36,000 tons, the total for the first quarter being 98,579 tons, compared with 107,420 tons for the same period of last year. The reduction in output at Springhill is, of course, due to the fire in the mine which took place around New Years. This difficulty has been overcome, the March output being about 3,000 tons in excess of last March. The net increase from the Dominion Company's mines for the first quarter compared with last year amounts to 118,830 tons. In April the Glace Bay mines will likely produce around 405,000 tons, or 25,000 more than last April. Shipments will not be quite so heavy in this month as last year, when it will be remembered the Cape Breton mines were sending many cargoes of coal to replace English orders because of the English coal strike.

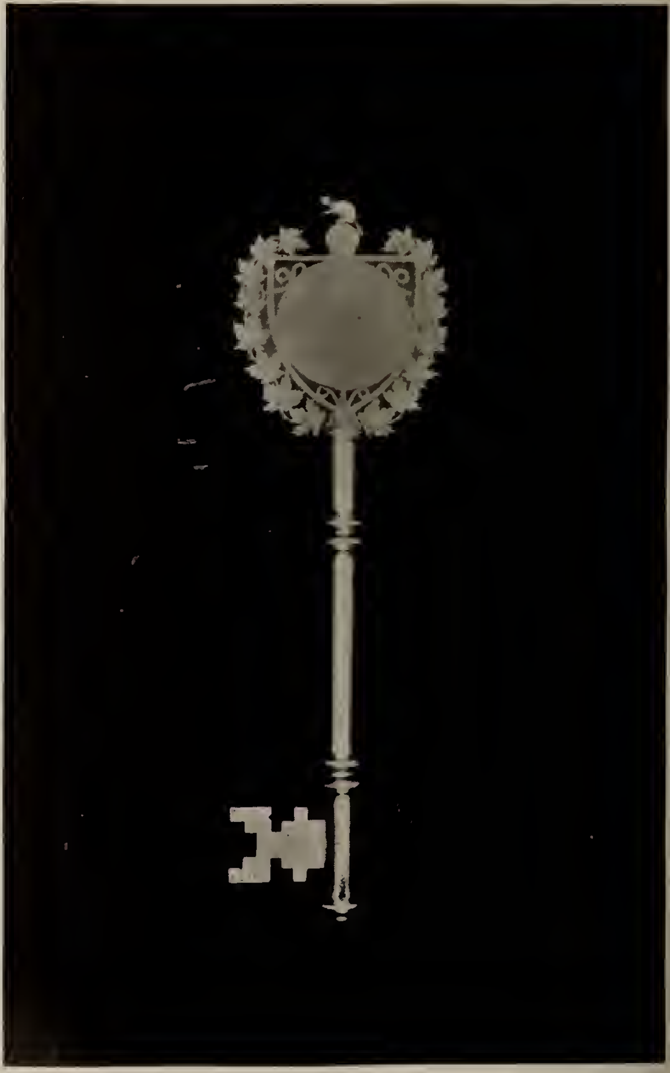
The Emery seam at No. 3 Colliery was pumped out towards the end of March, and a small daily output is now being obtained, which will rapidly increase to two or three hundred tons per day before the end of the summer. This mine is to be known as No. 11 Colliery. It is situated quite near to the surface works of No. 3 Colliery, a mine on the Phalen Seam approaching exhaustion. The opening of the Emery Seam will enable the company to utilize the existing plant and workmen's houses. It may be expected that this procedure will eventually be followed at all the company's mines on the upper seams. Up to the present, with the exception of two openings on the Emery Seam, the lower seams have been left untouched. Below the phalen Seam are the Emery and Gardiner Seams, each of them averaging between four and five feet of good coal, and with roof conditions eminently suited for the longwall method of extraction. Below these two seams are several others, not yet thought of as very attractive seams, but destined some day to be valuable. There are seams of coal in the Sydney Coalfield, as yet despised and disregarded which placed in some of the more exhausted coalfields of the world would be highly thought of. The coal from the Emery Seam it may be remarked is an excellent steam coal. It is a rather dull coal in appearance, having a long "reed" and is fairly strong in texture. It contains a rather larfer percentage of ash than the Phalen Seam, but in burning the coal does not clinker and the ash residue is light in texture and does not clog the draft. The sulphur percentage is low, and the heat units approach those of the Phalen seam. The volatile is comparatively low, and in every respect the Emery coal fulfills the requirements of a steam coal, and for this purpose it will steadily grow in favour when its merits come to be realized.

The unwatering of No. 17 Colliery is proceeding as quickly as possible. The railway connection will be put through during the coming summer, but it is not likely that any output will be obtained until late in the autumn. For the shipping season of 1914 this mine should prove an important producer.

# ONTARIO

### COBALT, SOUTH LORRAIN, GOWGANDA, AND ELK LAKE.

The last obstacle to the pumping out of Kerr Lake has been removed in the sale of the Drummond mine to Mr. David Fasken, and through him it is understood to other parties. One of the stipulations in that sale was that the riiparian rights of Kerr Lake should be sold to the Crown Reserve and the Kerr Lake for $250,000 so that cuts down the net price of the old mine to $250,000, which in the greatly improved condition of it is considered not too high, as there is no small amount of ore actually blocked out.



**Gold Key presented to Mr. Englehart, Chairman T.N.O. Ry., on the completion of the Elk Lake Branch.**

It is probable that Kerr Lake will be pumped out. All that is necessary now under the new clause in the mining act is for the companies to apply to the Mining Commissioner and get his permission to go ahead with the work after he has given his decision.

Plans are being quickly matured also to drain Cobalt Lake, bought from the government five years ago for over a million dollars. The company has twice driven into an open seam and been obliged to seal up for years some of their richest ore. Now they are rapidly preparing to put electric pumps on scows which will drain off the water into Farr Creek and into Lake Temiskaming. The lake is about three-quarters of a mile long and will probably average fifty feet deep so that the task will be of considerable duration. It is in fact estimated that it will take from four to five months steady pumping to lower the water to its required level. At the south or McKinley-Darragh end of the lake a dam will be thrown across the small creek leading into Little Lake and so into Bass Lake and Mud Lake. Enough water can be stored in this way to maintain the requirements of all the steam plants on the lake, it is anticipated. The task is naturally arousing considerable curiosity in the camp.

During the month of March the Nipissing mined ore of an estimated net value of $234,530, and shipped ore of an estimated net value of $204,910. At 63 shaft, which was put down on the old Meyer vein the most favourable development during the month was on the Little Silver vein. The raise was started from the 145-foot level to connect with the bottom of the old workings a hundred feet deep. The location of this raise was at a barren place in the vein, but after raising twenty feet ore was encountered which has averaged three thousand ounces over a width of two inches for forty feet. At a height of fifty feet the vein has become low grade. As soon as the ventilation is obtained by connecting with the Little Silver shaft other raises will be started on and also connect with vein 67, which shows one inch of two thousand ounce ore for sixty feet at the sixty-foot level. At No. 8 shaft crosscutting at the 125-foot level has encountered several small seams of no value. Drifting on one of these which runs in the direction of the surface open cut has now been commenced. This open cut produced a small tonnage of high grade ore from a vein which averaged eight inches wide. This formation both at the surface and at the level is lamprohyre, a keewatin rock. This is the first work done in the formation. The high grade mill treated 113 tons of ore and shipped 313,318 ounces of fine silver. The low grade mill treated 6,233 tons during the month.

The Trethewey production for the first quarter of the year was 150,000 ounces. This was a falling off in comparison with previous quarters due to the fact that during one week in February the mill was closed down on account of repairs which lessened the production. Had not the work at the mill delayed work the silver ounces would have been increased by upwards of 10,000 ounces. During the month of March the output was over 60,000 ounces of silver.

The McKinley-Darragh-Savage production for the first quarter of the year was 430,923 ounces. Of this the Savage contributed but 50,000 ounces. The Savage by months has only been from 17,000 to 25,000 ounces owing to the fact that no more ore is being thrown on the dump than is possible until the addition to the mill at the McKinley-Darragh mill has been completed. Then the low grade will go direct over aerial tramway to it and the production of the Savage will be doubled at once.

The figures for the Cobalt Townsite Mining Company for the first half of April are 80,900 ounces. For the week ending April 12 the amount of silver ounces produced was 40,400 ounces. This compares with 40,500 ounces for the previous week.

A strike of importance to the camp in general and to the mines in South-Eastern Coleman in particular was made at the Beaver Consolidated at the 700-foot level recently. The vein entirely in the diabase is three inches wide and of very high grade ore. Previously to the striking of high grade the Beaver had high grade ore on 600 feet, the deepest point attained in the camp at that time. The main vein at the 700-foot level was encountered a few weeks ago, but in the first twenty-five feet of drifting on it the vein failed to show any high values. It was not until the round fired last week that the ore shoot was encountered. The Temiskaming has also now a hundred feet of high grade ore below the Keewatin on their bottom level. It is significant that the vein systems in the diabase are new and not continuations of those mined in the keewatin above.

An interesting transfer of property was made by the Wallace syndicate, a number of Cobalt business men, to the Cobalt Aladdin Mining Company. Some time ago the Wallace syndicate bought both the Right of Way and the old Silver Queen dumps for a nominal price. They have shipped several cars of ore and declare to have made a good profit. It is certain that the ore in the old Silver Queen dump did run surprisingly high. The Wallace syndicate had a contract with the Nipissing Reduction mill to run their ore, and the Cobalt Aladdin wanted it to treat Chambers-Ferland low grade. The Cobalt Aladdin has now bought the two dumps and also taken over on a lease the Nipissing reduction mill.

### PORCUPINE SWASTIKA AND KIRKLAND LAKE.

The disaster at the Waiwaiten Falls plant will seriously incommode many mining companies in the Porcupine camp though its seriousness is relieved by the fact that the Sandy Falls plant is still working and most of the companies have steam plants of their own; both penstocks were broken, and some of the masonry under them swept away. It is hoped to have the damage repaired in upwards of a months time.

The effects of the strike have now almost disappeared and nearly every company desiring to operate at once is working. The Jupiter is using its own steam plant.

The Foley-O'Brien is to be operated again by a Buffalo syndicate, who have purchased the control. The Moneta is being diamond drilled. The Three Nations has all its mill machinery on the ground, the Hughes is operating its small stamp mill, and the Schumacher is now installing a big compressor plant with the plan of commencing development on a considerable scale. Mr. Joe Houston cut two veins, both promising with his diamond drill and is now going underground. The camp is very busy and experts to be still busier. The Dome and the Hollinger are now on a steady producing basis.

The strife between union and non-union men was stirred up again by a drunken brawl at Timmins when a non-union man shot at a striker for insulting him, but the Provincial police were in strong force and no disorder followed. The merchants are gradually recovering from the effects of the strike, though they have suffered most.

Practically all the foot loose prospectors in Northern Ontario are in or near Kirkland Lake. The surprising richness of the Foster Tough vein and the fact that it has endured to a depth of over a hundred feet has aroused surprisingly little excitement outside. The Foster Tough property has paid from the grass roots down and it now is looking remarkably well. There is no doubt whatever that in a few months, perhaps weeks, the public will be taken into the confidence of many syndicates and importuned for their own good, their own health and happiness, to make a hundred per cent. by financing some prospect. There are all the earmarks of a boom.

There appears to be no doubt of the promise of the district. The veins, though quite narrow, are much richer (that is they have been demonstrated so on two or three properties) than in Porcupine, and the operator is not plagued by the faults that makes the mine manager's life in the older gold camp a burden. The western engineers who have visited Kirkland Lake declare that conditions appear more familiar to them than at any other point in Northern Ontario, and they are certainly fore favourably impressed with it than any technical man who valued his reputation was with Porcupine at the same stage of development. Quite a number of deals have been negotiated though for no every large sums. The Great Northern Silver Mines have taken over the control of the Hughes, the second property in the section, and it is understood that it will be mined under the capable direction of Mr. John Redington. The Cobalt Aladdin, before exclusively busied with silver in the North, has rushed in and purchased the Burnside and is showing no tardiness in developing. A plant has been ordered already and a gang of men have been put to work at once. So far the development of the camp has been singularly healthy and free from inflation and boosting, but it is scarcely to be expected that it will remain so long. Swastika will probably remain the centre of settlement, and it is now quite busy after many lean years. At Swastika itself the Swastika mill is now making a little money for the pioneer company of the camp, and the mill at the Lucky Cross should be running soon. It is reported that the development at the Lucky Cross has been quite satisfactory lately.

## BRITISH COLUMBIA

The near approach of the time at which, under existing provisions therefor, the payment of bounty on lead mined and smelted in Canada will cease, is causing concern among lead-mine owners as to the intentions of the Federal Government with regard to the future. While it is generally believed that Government assistance will be continued in some form or other nothing definite has yet been publicly made known, so that there is uncertainty in the matter. While a considerable proportion (nearly one-third of the total to each, of the amount paid during the last calendar year was earned by two companies, there were at least twenty owners in West Kootenay district who also benefited, though in varying degree. In connection with this question, the following reference to lead production, taken from the Kaslo Kootenaian, is of interest: "Mr. G. O. Buchanan, Supervisor of Lead Bounties, states that the lead production in the month of February was about the largest in any month in the history of lead mining in the Dominion, a total of about 3,000 tons of lead having been produced by the mines and smelteries during that period. The greater part of this came from Ainsworth and Slocan mining divisions."

**Nelson.**—On March 13, according to The Daily News, a meeting of members of the Nelson board of trade passed a resolution as follows: "That this board feels assured, from the proofs submitted of the existence in this district of platinum and regrets the publication of the opinions of Mr. W. Fleet Robertson and Mr. E. Jacobs to the contrary until the matter has been more thoroughly investigated, and that a committee of three be appointed to act with the secretary in writing to the Minister of Mines and calling his attention to the damage being done to the mining industry of this district by such statements as have recently appeared." The committee appointed consist of Mr. C. R. Hamilton, barrister; Mr. R. W. Hinton, mechanical engineer; and Mr. J. O. Patenaude, jeweler. One of the men most prominent in the discussion that took place was Mr. Fred A. Starkey, formerly a grocer and provision merchant, now a "mining broker" and real estate agent, who was reported by The Daily News in part as follows: "Mr. Starkey declared that the report should never have got beyond the office of the Minister of Mines; that it was a 'disgrace to the country,' because it 'slandered this section of British Columbia.' He asserted that Mr. Robertson as a scientific man was not in any way the equal of Mr. A. Gordon French, who announced the discovery of platinum in this district."

(Incidentally, it may be mentioned that E. Jacobs did not publish any of his "opinions," but only the official report. Further, there was not at the meeting a mining engineer or mine manager of recognized good standing.)

On April 11 The Daily News published, under the heading "Platinum Report is Favorable," the following: "Board of Trade Committee Believes Metal Exists Here, but Cannot Say as to Quantities. Having received 22 copies of platinum assays of rock taken from the Nelson district in which values in platinum and other metals of that group were shown the special committee, consisting of C. R. Hamilton, K.C., R. W. Hinton, and J. O. Patenaude, appointed by the board of trade, reported last night stating there was every reason to believe that the metals existed here. The committee stated that it could not, of course, state if the metals were in commercial quantities, but suggested that a letter should be sent to the Minister of Mines regretting the publicity given to statements by W. Fleet Robertson, provincial mineralogist, and E. Jacobs, and asking for a further investigation. Fred A. Starkey stated last night that eight of nine assays had recently been received in the city from Philadelphia giving returns as high as $18 in platinum, in addition to gold. R. W. Hinton remarked that the high values did not necessarily prove the existence of the metal in commercial quantities, unless a careful sampling of a lead had been made. They were, nevertheless, an encouragement toward investigation."

**Rossland**—The fololwing editorial comment was published in the March number of The Mining Magazine, London: "The law of extra-lateral right, though founded on justice to the original discoverer of an ore deposit is apt to act preferentially toward the lawyers and the expert witnesses. The very mention of the name evokes visions of interminable lawsuits. We have, therefore, nothing but the sincerest congratulations to offer to the Le Roi No. 2 and the Consolidated Mining and Smelting Company of Canada for their wisdom in effecting a compromise in connection with the conflicting rights arising from their adjoining groups of claims at Rossland, British Columbia. The disputed ground lay in the Le Roi No. 2 property and it was claimed to belong to the Le Roi property, purchased a year ago by the Canadian company. The necessity for some such readjustment of interests was fully known to the directors before the Le Roi property was sold to the Canadian company, and the directors of the Le Roi No. 2 were therefore not unprepared. Le Roi No. 2 transfers portions of the No. 1 and Josie claims, together with certain underground rights to the Consolidated, and in return acquires the Moneta claim. The possession of the latter ground will greatly facilitate the development of ore bodies in the northern end of the Le Roi No. 2 property."

The quantity of ore produced from Rossland mines during the three months ended March 31 was approximately 63,000 tons. With the exception of less than 200 tons from several small shippers, the mines of The Consolidated M. and S. Co. and Le Roi No. 2, Ltd., made this production in about the following proportions: Consolidated Co.'s Centre Star-War Eagle group, 37,000 tons; Le Roi mine, 15,500 tons; total 52,500 tons. Le Roi No. 2's mines: Ore shipped, crude and concentrate, 5,500 tons; ore concentrated, 5,000 tons; total 10,500 tons. Mining operations in connection with the smaller properties continue to be comparatively unimportant. The Blue Bird has not been a producer for several months, and the Phoenix and Nickel Plate have shipped only small quantities of ore. It has been announced that the Richmond Consolidated intends to work its property, situated in the South Belt, also that it is intended to develop the San Francisco on a small scale under lease.

**Boundary District.**—The following is part of a long report published in this district, stated to have been taken from the annual report of the British Columbia Copper Co., this covering a period of thirteen months, to the end of 1912: At the company's smeltery at Greenwood, Boundary district, there was treated 740,589 tons of ore, of which 443,022 tons was from the company's mines, while the remainder was custom ore. The metals produced were 11,146,811 lbs. of copper, 142,025 oz. of silver, and 25,862 oz. of gold, these having an aggregate value of $2,483,663. The yield of copper, gold and silver, was less per ton than for any previous year, while the cost per ton for handling, etc., was lower than in any other year. Notwithstanding this low cost of handling the ore, the cost of producing copper was 12.85 cents per pound, the low yield of metals being accountable for this comparatively high cost. The net financial result of operations was a profit of $425,885.40 (the largest in the history of the company) from which amount there were paid during the period covered by the report two dividends, these aggregating $177,512. During the fiscal year the company paid on account of new properties, and for exploration and development work done on them, $229,489. This expenditure was made because of the great importance of supplementing the company's ore reserves. In addition, there was added to the company's holding of New Dominion Copper Co. securities, bonds of the par value of $238,675, these having cost $122,249.25.

Ore production during the three expired months of the year has been about 290,000 tons from the Granby Consolidated Co.'s mines at Phoenix, and 145,000 tons from the British Columbia Copper Co.'s Mother Lode and Rawhide mines. Small quantities were produced by several other properties, including about 700 tons from the Consolidated M. and S. Co.'s No. 7 mine, but these were unimportant about 3,000 tons in all.

Early in April the annual meeting of the Boundary Mining and Exploration Co. was held at Midway. Shareholders were informed that development work is resulting satisfactorily. Fourteen men are employed, machinery is being installed, and an incline shaft is being sunk from No. 2 tunnel to the coal.

**Coast District**—In the lower coast district metal mining operations are confined largely to three or four properties. In Vancouver mining division an organization known as the Lynn Creek Zinc Mines, Ltd., has for some time been developing a group of claims situated in the vicinity of Lynn Creek and distant about ten miles from Vancouver City. At the Britannia, in the same mining division, such further good progress has been made that since April 1st full time has been worked in all departments, excepting in the long cross-cut adit in which last two shifts, instead of three, are employed. The output of ore is being regularly maintained up to the treatment capacity of the concentrating plant, and shipments to the smeltery are again normal. Having sufficient men for development in addition to mining, that work has been resumed throughout the Britannia company's extensive property. Good progress is being made with the various improvements in hand, these including provision for the development of more hydro-electric power, construction of a railway from the face of the new tunnel down to Britannia Beach (about four miles of track), erection of new buildings in both the Beach and Tunnel camps, and the completion and equipment of a new concentrating mill.

No information has been received lately relative to the Tacoma Steel Co.'s Marble Bay mine, near Van Anda, Texada Island, but last advices were to the effect that only development work in the lower levels was being done, ore-production having been temporarily stopped.

On Vancouver Island, the situation is being gradually improved at the coal mines of the Canadian Collieries (Dunsmuir) Limited. Figures published at the beginning of April showed that during the week ended March 28 the output of coal from the company's Union Colliery mines, Cumberland district, was 8,891 tons. Miners have been arriving at Cumberland from various parts, including some from Great Britain, and matters generally are steadily approaching a position similar, as regards operation of the mines and production of coal, to that existing prior to the strike declared about seven months ago. A beginning has been made at the company's Extension colliery, as well, and it is stated that about 200 men are now at work there.

# COMPANY NOTES

## CROW'S NEST PASS.

The report of the Crow's Nest Pass Coal Company has been distributed. The net profits were $471,454 and, deducting from this a debit of $52,030 brought forward from the previous year, leaves a profit and loss surplus of $419,424.

The net profits were at the rate of 7.58 per cent. on the paid-up capital stock.

Coal mined during the year was 1,064,791 tons, compared with 359,456 tons in 1911; while coke produced in 1912 was 245,229 tons, against 60,659 tons in 1911. During 1911 the mines were closed down for eight months on account of the strike of miners.

**Balance Sheet.**

The balance sheet and profit and loss account follow:

| | 1912 | 1911 |
|---|---|---|
| Balance | *$ 52,030 | $210,734 |
| Dividends received | 786 | 10,484 |
| Profits | 470,668 | 52,094 |
| | $419,424 | $273,312 |
| Loss on operation | | 263,232 |
| | $419,424 | $10,080 |
| Dividends paid | | 62,110 |
| Surplus | $419,424 | $52,030 |

*Debit balance.

Liabilities.

| | 1912 | 1911 |
|---|---|---|
| Capital stock | $6,212,666 | $6,212,666 |
| Profit and loss | 419,424 | .......... |
| Insurance fund | 26,072 | ......... |
| Bills payable | 1,212,437 | 1,634,612 |
| | $7,870,599 | $7,847,278 |

Assets.

| | 1912 | 1911 |
|---|---|---|
| Mines, etc. | $6,478,705 | $6,720,340 |
| Securities | 776,753 | 815,160 |
| Accounts receivable | 347,861 | 256,302 |
| Cash | 113,703 | 3,446 |
| Profit and loss | ....... | 52,030 |
| Inventories | 153,577 | ....... |
| | $7,870,599 | $7,847,278 |

During the year the amount spent on improvements charged to capital account was $19,976.31, and the amount spent on development charged to capital account was $18,418.58.

The Crow's Nest Pass Electric Light and Power Company, Limited, carried forward to the credit of profit and loss account, last year, $1,134.73. The profits for the year 1912 amounted to $5,863.81, making the total amount at the credit of profit and loss account of that company, December 31st, 1912, $6,998.54.

The Morrissey, Fernie & Michel Railway Company carried forward a loss last year of $7,002.31. That loss has been made up during the year, and there is now $25,078.49 at the credit of profit and loss account, or a total profit of all companies for the year 1912 of $509,398.77.

President Rogers points out that during the year the indebtedness to the banks had been reduced to $568,099. At the end of the year it stood at $795,000, and since the end of the year the company has paid $70,000 more to the First National Bank, leaving the indebtedness now standing at $725,000.

### ANNUAL MEETING MARITIME COAL.

At the annual general meeting of the shareholders of the Maritime Coal, Railway and Power Company, Limited, April 22nd, the following were elected directors for the ensuing year: Wm. Hanson, A. E. Dyment, Alex McLaurin, Wm. Ewing, G. Ratcliffe Hume, W. L. Madgen, Hon. Senator Wm. Mitchell, and Hon. Senator N. Curry.

The president reported that the negotiations for the sale of a considerable block of the company's securities had been successful, and it was contemplated to carry out, during the ensuing year, large extensions to the power plant at Joggins' Mines, to cope with increasing demand for coal and electric power.

Wm. Hanson was elected president; A. E. Dyment, vice-president, and R. Wilson, secretary.

### GRANBY'S MARCH FIGURES.

Granby's operations at Phoenix and Grand Forks for the mont hof March showed a profit of $87,770, and for the nine months of the fiscal year $990,255. The yield of metals has been fully maintained, and the cost of copper for March slightly reduced, but current profits for a portion of this period were interfered with by the decline in the price of metal. All figures are now based on 4½, copper, and on the 31st of March we had on hand 1,935 tons taken in at that figure. Reports from the development work of the old properties indicate that ore reserves there have been fully maintained.

### BEAVER CON.

At the annual meeting of the Beaver Consolidated Mines, held in Toronto on April 22nd, it was pointed out that the finances of the company at present did not warrant the declaration of an April dividend, owing to the large amount of money being spent in development work. It was stated, however, that the directors expected to be able to declare as many dividends as in 1912.

# STATISTICS AND RETURNS

### COBALT ORE SHIPMENTS.

**Week Ending April 19.**

The shipments for the week, in pounds, are:

| Mine. | High | Pounds |
|---|---|---|
| O'Brien | 1 | 78,668 |
| Right of Way | 1 | 62,136 |
| Coniagas | 2 | 102,971 |
| McKinley-Darragh | 2 | 121,884 |
| Dominion Reduction | 1 | 83,612 |
| | 7 | 439,271 |

The bullion shipment for the week was:

| Mine | Bars | Ounces | Value |
|---|---|---|---|
| Nipissing | 107 | 130,357.74 | $78,214.64 |

The bullion shipments to date are:

| Mine | Ounces | Value |
|---|---|---|
| Nipissing | 1,437,906.21 | $840,486.98 |
| Buffalo | 464,422.50 | 282,308.76 |
| Crown Reserve | 108,891.00 | 72,394.00 |
| Temiskaming | 4,000.00 | 2,228.00 |

# PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assaye Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

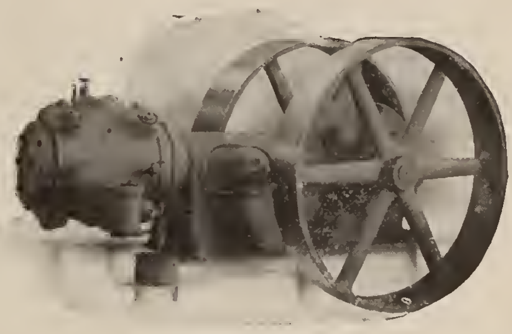
*THESE new moderately high speed, medium sizes compressors embody many valuable ideas peculiar to this design only.*

*No other machine so successfully meets the demand for moderate sized compressors.*

*While they are called small compressors they deliver more air per foot of floor space or per pound of machine and deliver it constantly over a longer period and at a lower cost than any other similar machine on the market.*

*Our reputation is substantially back of this Class "N" design and the satisfactory operation of every one of these compressors is absolutely assured.*



CLASS "NE-1."

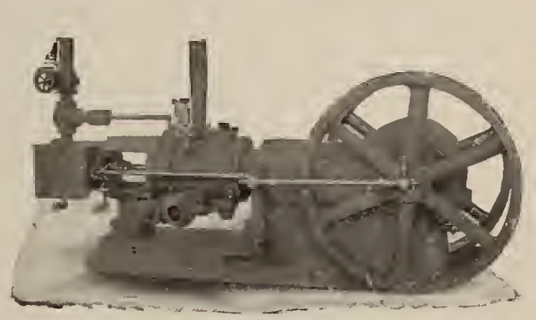
CLASS "NE-2."

**Class "NE-1" is a Single Stage Belt Driven Type.**

**Class "NE-2" is a Two Stage Belt Driven Type.**

**Class "NF-1" is a Single Stage Steam Driven Type.**

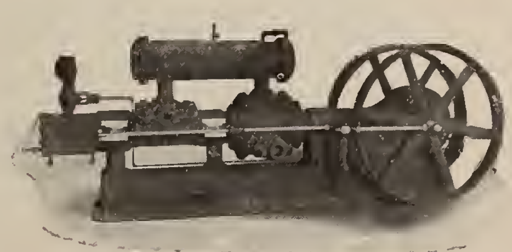
**Class "NF-2" is a Two Stage Steam Driven Type.**



CLASS "NF-1."

*All built on the same rugged, reliable, self-contained general design. Classes "NF-1" and "NF-2" are convertible from steam to belt drive or vice versa.*

*Capacities ranging from 57 to 426 cubic feet of free air per minute at pressures from 15 to 100 pounds.*



CLASS "NF-2."

## Twenty Minutes or One Half-Second?

How long does it take you to get a message to and from the far end of the workings? If you must send a man, you know how long it will take him. A wait for the bucket—a trip down—the long walk to the far end—back again—another wait and then up the shaft—twenty minutes at the least.

With the **NORTHERN ELECTRIC MINE TELEPHONE**

It takes one half-second to reach any part of the mine—the engine room—hoisting shaft—main entry—anywhere.

On the score of time saving alone, the Mine Telephone is one of the best investments you can make.

It changes the mine from a number of disjointed departments, isolated by distance, to a compact organization, working together with the greatest efficiency under one head.

In an emergency, the Mine Telephone makes it possible to send warning and give instructions to all departments simultaneously.

For full particulars write our nearest House

CONTENTS.

## LEGISLATURE NEEDS

The session at Ottawa is drawing to a close. Nothing has been done as regards mining legislation, nor is there much possibility that anything can be done this year. The Naval Bill has, of course, occupied almost completely the attention of the House. And this has been but one of the evidences of the costliness of His Majesty's Loyal Opposition. How far the blocking tactics may have been necessary from a political point of view is not for us to say. Yet we believe that we are expressing the view of the generality of Canadian citizens when we state that the whole naval incident, or series of incidents, has been nauseating. Not only has the proper administrative business of the country been relegated to the background, but a large number of urgent questions have been given no consideration whatsoever.

Some weeks ago we drew attention to the carelessness of the Dominion Government's attitude towards the mining industry. Let us here quote one paragraph from our published editorial:

"There has been ample mincing of words and phrases heretofore. The Canadian Mining Institute, through its delegations and at its meetings, has voiced the desire of the mining man for better treatment. Whilst its delegates have walked softy and talked politely, they cannot have failed to impress upon the Rt. Hon. Mr. Borden and his Ministers the fact that the Institute as a whole deplores and resents the futility of the past and present situations. Briefly, therefore, the treatment accorded the mining industry appears to be calmly deliberate."

As a corrective to this Governmental indifference we urged the organization of mining men into an organic entity that would count politically. The longer the present circumstances are permitted to exist, the more pronounced will the industry's grievance become. It matters not whether it be the Naval Bill, or any other disturbing factor, we are convinced that the Government will not give due consideration to mining affairs until it is forced to.

As a piece of constructive legislation there is nothing more needed than a uniform Canadian mining law. True, it will take much effort and much time to bring about a clear understanding between the various Provinces and the Dominion. The proposed law will be a process hather than an event. But it is high time that a start were made. We are losing prestige with every day of delay.

To bring the whole matter to a head, we would propose that the Canadian Mining Institute, the only organization that can be utilized for the purpose, canvass its members for an expression of opinion. To this end it will be necessary that a draft of the representations be printed and circulated. The membership of the Institue is abundantly comprehensive. A plebiscite of this kind will be instructive and impressive. To the argument that such a step might be bad politics, we would reply that there is not the slightest need of considering political expediency as it is self-evident that the mining industry gets little consideration from the politician.

In closing, we may remark that the present Dominion Government is obviously ignorant of the needs of the industry that we have the honour to represent. If it is not ignorant, then the only conclusion is that it does not care—a painful and pregnant conclusion.

## THE OTTAWA LABORATORY

On another page we reproduce a list of the mechanical equipment installed in the new ore testing laboratory of the Dominion Mines Branch at Ottawa. The official designation of the laboratory is the Dominion of Canada Ore Dressing and Metallurgical Laboratory. The object of this establishment is to supply to the mining public of Canada a means whereby large lots of ore can be efficiently tested.

The equipment appears to be well chosen and complete. One of the chief items is a 5-stamp battery. The cyanide testing outfit, although of laboratory size, is capable of handling sufficiently large samples. The minimum limit for small scale tests is placed at 200 pounds, for large scale tests the samples must be at least five tons.

The Mines Branch reserves the right to publish the results of all tests.

While at several of our universities there are ore testing establishments, no private individual has yet organized one in Canada. There are, it is true, several customs mills and one large shipment sampling plant in Canada, but these handle silver ores only.

While we are entirely in sympathy with the movement, it must be pointed out that extreme care should be taken not to overlap or compete with the work of the private assayer. It must also be remarked that there is danger of the official Government report being misused. Unfair sampling may easily lead to complications, and be made the basis of raising money for mining schemes.

Moreover, there is room for much difference of opinion as to the relative value of large scale and small scale tests. It does not follow that because five tons or twenty tons have been milled, the results are more accurate tha nthose obtained from careful sampling on a small scale. Naturally, much can be learned by means of the larger tests as to treatment. But it must always be borne in mind that mechanical considerations make the control of any given sample shipment a matter of extreme difficulty, whereas the small laboratory sample can, with proper care, be depended upon for accurate results.

We repeat, therefore, that whilst we wish the new enterprise all success, we think it most necessary that every pains be taken not to interfere with private assayers.

## THE NIPISSING REPORT

According to the eighth annual report of the Nipissing Mines Company, just issued, the operations during the calendar year 1912 were highly satisfactory. Dividends to the amount of $1,800,000 were distributed, the sum of $240,000 was added to the surplus, and the ore reserves were increased by 1,750,000 ounces. In addition, the new "low grade" mill, costing $325,000, was paid for out of earnings.

The total silver produced was 4,688,260.79 ounces, having a gross value of $2,896,990.10, and costing altogether $815,279.95, or 17.39 cents per ounce. General operating expenses accounted for 12.08 cents per ounce, high grade milling for 2.12 cents, low grade milling for 0.66 cent, and depreciation for 1.12 cents. The average price received for the silver was 61.457 cents per ounce.

Nipissing, up to the end of last year, had paid $10,-168,297.25 in dividends. Of this magnificent total more than 70 per cent. was distributed in the last four years. On account of the large territory to be prospected, the exploration charges are high, and will probably remain so for some years to come. Of drifting, crosscutting, raising, and sinking, a total footage of 13,020 feet was covered during the year, and 15,764 cubic feet stoped. During the summer, 33.2 acres of ground were hydraulicked, an expeditious and efficient means of prospecting, far more satisfactory than the costly trench. Although most of this territory had been trenched before, numerous small veins and stringers were discovered.

With ore reserves carrying a total of nearly ten millions ounces, with a surplus of $1,443,953.09, and with an admirably complete plant, Nipissing is in an enviable position.

## EDITORIAL NOTES

International Geological Congress preparations are going forward smoothly. We may venture to suggest that thoroughly organized newspaper publicity should not be neglected.

Gold mining in Nova Scotia, quiescent as it may seem, is not yet dead. Four properties are being examined by American engineers at present, and there are other symptoms of activity.

## MORE ALCHEMY

The high-water mark for pure and applied nonsense has been reached by Mr. G. W. Rumble, of South Berkeley, California. Rumble even eclipses our lamentable friend, Mr. Thurber, who, our readers will remember, was the father of a process for getting gold out of any old rock.

Mr. Rumble's idea is ostensibly the application of a "new, simple, cheap, efficient solvent" to refractory ores and black sands. In his own elegant phraseology "it's a Salts." A flat cost of 25 cents per ton of ore is indicated. "Come on" invites the rambling Rumble.

The strange fact is that somebody will be sure to "come on." The Rumbles and the Thurbers and all the varieties of the type find easy victims in the unthinking public. It is not probable, however, that Mr. Rumble's career will be either long or glorious.

### ORE SOLVENT.

I have a new, simple, cheap, efficient solvent for refractory ores and Black Sands whereby the refractory condition of the ore is neutralized so the values go into the Quick. Gold. Platinum.

It comes nearer to recovering ALL the values than any other known method.

It's a Salts, to be wholly dissolved in water, 48 water to 1 salts.

Cost for Salts, 25 cents per ton of ore.

### FOR PLATES IT IS THE BEST ON EARTH.

It prepares copper plates to take and hold the Quick and keeps them in condition the best ever.

Come on, I have a small Laboratory and test plant here. Will tell and show you all, and send you sample of Salts so you can test.

(PATENTED)

G. W. RUMBLE.

**THE MINING MANUAL AND MINING YEAR BOOK —1913. Price, $5.00. Published by Walter R. Skinner, London, E.C. For sale by the Canadian Mining Journal.**

From year to year Mr. Skinner's directory increases in size and value. It is one of the prime necessities of the mining investor or engineer who has business relations in other countries.

It contains in this annual addition particulars of 3,050 mining companies. In addition to this, it gives the names of 5,300 companies, 6,000 directors and 1,300 secretaries are listed, and the names and addresses of 1,200 mining engineers and managers are given. The amalgamation of the Mining Manual with the Mining Year Book (formerly published by the Financial Times), widens the scope of the directory so as to include nearly all the important mining companies of the world.

We note with regret that Mr. Skinner in his prefatory review, avers that "the Porcupine field has quite failed to answer expectations." This is not the case and we would suggest that an apology is due.

---

Mr. George B. Burchell, formerly manager of the Joggins collieries, Nova Scotia, has removed to 274 Addington Avenue (Notre Dame de Grace), Montreal.

Mr. L. B. Orchard, formerly connected with the Londonderry Iron & Mining Company, has just returned from South America and is at present in Calgary.

Mr. G. C. Bateman recently visited Porcupine.

# THE WITWATERSRAND—THE CITY DEEP

By ROWLAND GASCOYNE.

**Transvaal.**

The City Deep mine is regarded as one of the coming mines on the Rand. Formerly this deep level area was not regarded with much favour, as several of the outcrop mines, notably the Spes Bona and New Goch have not been conspicuously successful, owing to the low grade of the ore, others like the Wolhuter, Meyer and Charlton and City and Suburban have excellent records. The work done by the City Deep has, however, disclosed a more than usually rich main reef leader, and the recovery values rank amongst the half dozen highest on the Rand.

Milling operations commenced just over two years ago, but during the short time that has elapsed since the stamps were first dropped, operations have not proceeded as smoothly as could be wished, either above or below ground. Many of the difficulties were trifling, but those underground were the most serious. The layout of the mine did not conduce to economical working, ventilation troubles arose, and, last, but not least, there was a chronic scarcity of native labour. These difficulties are being gradually overcome one by one, and at the time of writing 150 stamps out of 200 stamps originally erected have been got to work and last month the City Deep figured, by reason of its gold output, amongst the twelve leading gold producers in the Transvaal. vaal.

It was not until 1908 that by amalgamation with neighbouring mines that the City Deep assumed its present shape and importance, and to-day its total area is only one claim short of a round two thousand, a gold mining claim in the Transvaal measuring 154.95 English feet on the strike, 413.2 feet on the dip, being in area approximately 1½ English acres. The capital of the company is £1,250,000 in £1 shares. The company also possess an estate of over 3,500 acres upon which the workmen are offered building sites for the erection of their own dwellings on highly advantageous terms, with the object of inducing the white employes to settle, and not move from mine to mine as is usual on the Rand.

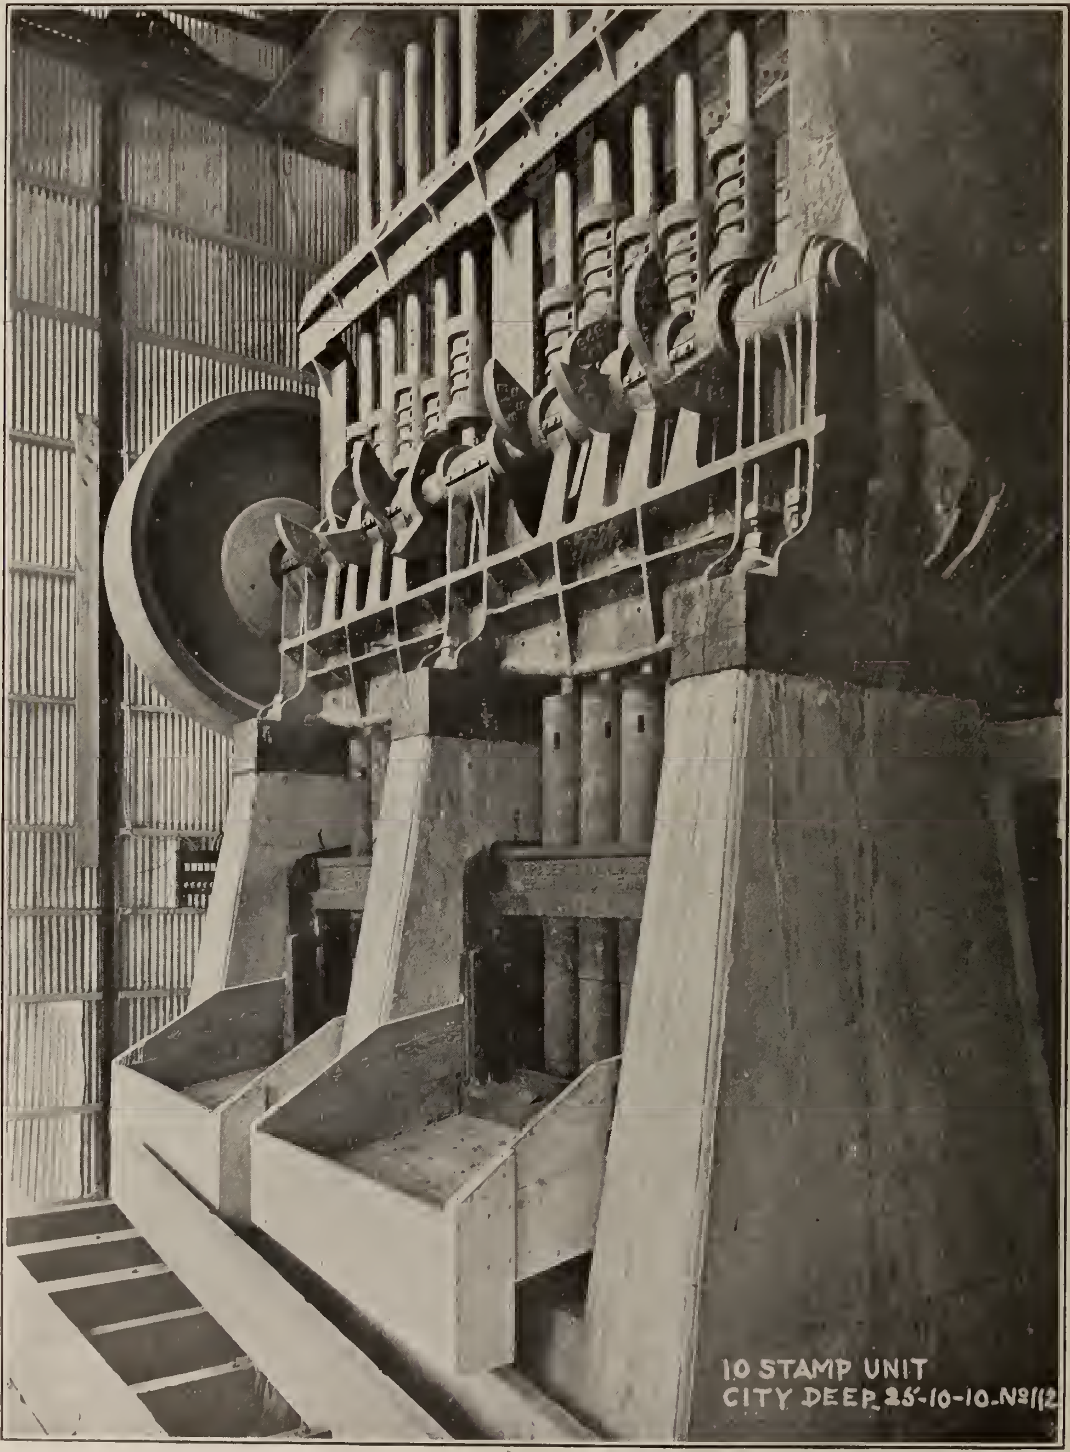
From east to west the property of the City Deep extends about two miles. Two vertical rectangular seven-compartment shafts have been sunk to the reef, each shaft measuring 44 feet by 8 feet in the clear. The No. 1, or eastern shaft, is 3,100 feet from the eastern boundary and 3,261 feet deep. Cross-cuts have been driven north from this shaft to strike the reef on the 8th and 9th levels, and sinking has been resumed with the object of striking the reef at a vertical depth of a little over 4,000 feet. 4,400 feet further west is the No. 2 or western shaft, where the reef was struck at a depth of 2,876 feet. This shaft is situated about 3,500 feet from the eastern boundary. It is the rule on the Rand to place the shafts considerable distances apart, a practice which has many disadvantages as regards ventilation, particularly before the shafts are connected, the value of which has only been recently recognized.

What is known as the main reef leader is the principal reef, little work having so far been done on the main seef or south reef, although it is possible that as in some of the neighbouring mines both these reefs may be drawn upon in the future. Several miles of driving on the main reef leader show that it is wonderfully consistent, both in width and values, the average width running twenty inches and the assay value twenty-two dwts. of gold to the ton. The reefs dip south at an angle of 38 degrees, the distance between the south reef and main reef leader varying from 60 feet to 80 feet, the main reef leader being apparently thicker in the eastern than in the western section of the property.

**No. 2 Shaft, Sorting and Crushing Station.**

The two shafts are situated about 2,000 feet south of the northern boundary of the property, thus leaving a larger area than usual to the rise which is worked through cross-cuts from the shaft. The proposed method of working is to drive main collecting levels 1,000 feet apart, designed to be fed by inclines from the dip by chutes from the rise. These main levels are at present worked by mule traction, but petrol locomotives are being fitted together on the property, with the object of displacing mule transport. They are of single cylinder horizontal type, 9-inch diameter, 12-inch stroke, horse power 25 to 30. The main levels are laid with a double line of heavy rails, the ore being conveyed to large ore bins at the shaft built of re-inforced concrete, and fitted with Kimberley chutes for rapidly loading the skips.

gear pulleys 16 feet diameter. The skips carry 5 tons, maximum speed of hoisting, 3,000 feet per minute, so that each hoist can raise 165 tons per hour. There is also an electric man hoist, three-phase type, driven by a 1,600 h.p. motor operated by power at 2,100 volts 50 cycles. The braking arrangements of this man hoist



**Californian Stamps**

are interesting. In addition to the usual post brakes worked by compressed air, there is an "eddy current" brake, the direct current being obtained at 120 volts from a rotary converter in the engine room or alternately from a storage battery. The drums are of cast steel, 11 feet diameter and 4 feet wide, each drum carries 4,200 feet of rope. The man cages are of the

It was intended to use electric power purchased from the Victoria Falls Co., exclusively, but as such was not available when wanted, a boiler plant of nine boilers was installed at No. 2 shaft. The hoisting plant consists of two double compound tandem Whiting hoists, with 17-inch and 28-inch cylinders and 5-ft. stroke. Driving sheaves 12 ft. diameter, ropes 1½-inch, head-three-deck type for carrying 20 men on each deck. Synchronous speed of motor 100 revolutions per minute giving a rope speed of 3,500 feet per minute.

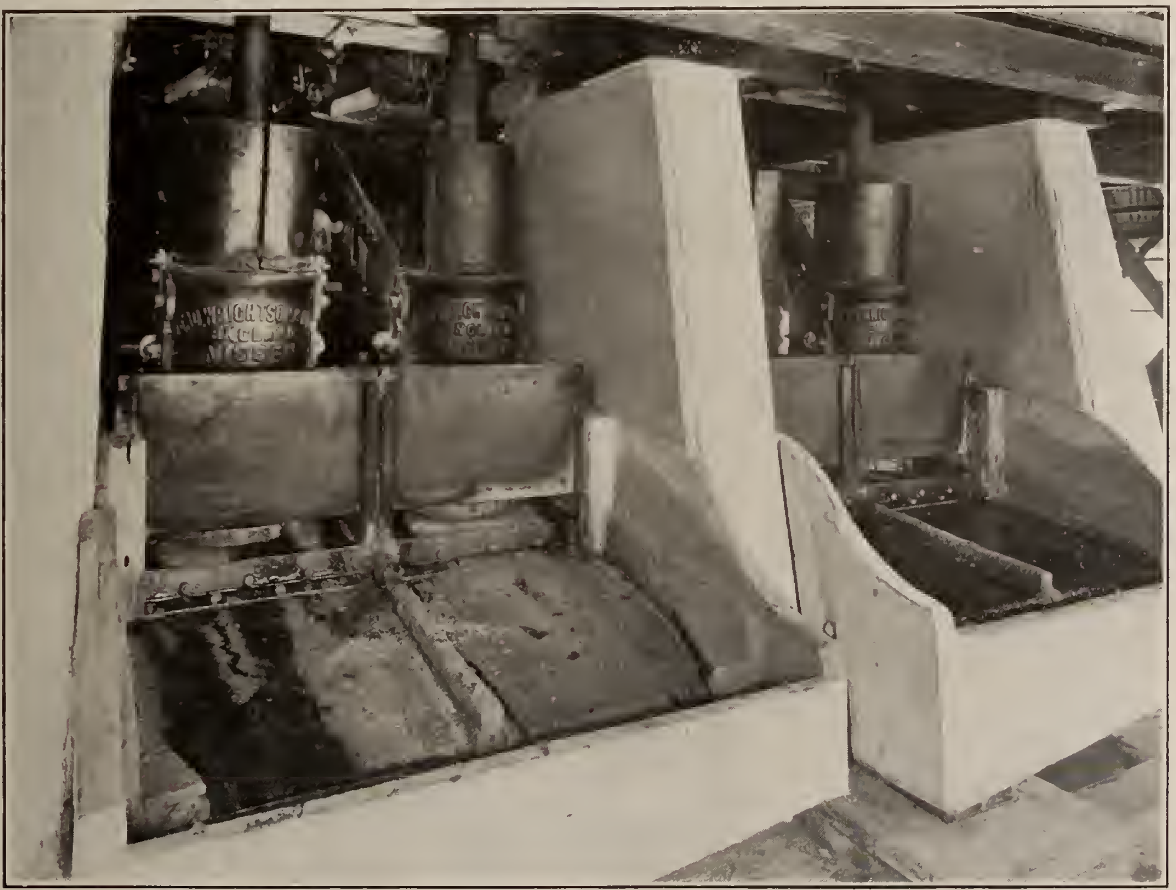
Both compressed air and electrical power are purchased from the Victoria Falls and Transvaal Power Co., the former being delivered at 110 lbs. per square inch, the electrical power by underground cables to sub-stantions at a pressure of 20,000 volts and transformed to 2,100 and 525 volts as required. There are some 120 motors on the property, aggregating 7,500 h.p. They vary in size from 3 h.p. to 1,600 h.p., those of 40 h.p. and over working at 2,100 volts and the smaller ones at 525 volts.

All the sorting and crushing at present is done at No. 2 shaft, the ore being passed over 1½-inch grizzlies and the fines conveyed direct to the crushed ore bin by a 24-inch belt, the coarse ore passing to four 36-inch. conveyor belts and washed by sprays to facilitate sorting, the waste being thrown on to the return side of belt. The sorted ore passes to twelve 30-inch by 12-inch Blake crushers, adjusted to give a product approximately 2-inch cube. Each crusher is driven separately by a 60 h.p. motor. The crusher ore bin is built of re-inforced concrete, fitted with doors worked by compressed air and has a capacity of 1,000 tons.

Forty-ton hopper trucks convey the crushed ore to the mill bin hauled by electric locos. Each loco consists of two units driven by a 150 h.p. motor of the three-phase type, the power being supplied through "buffer" transformers to overhead lines and eath.

The mill, originally of 200 stamps, has now 190 Californian and 4 Nissen stamps. The Californian stamps have a dropping weight of 1,650 lbs. and the Nissen stamps 2,000 lbs. The mill is arranged in units of ten stamps each, driven by a 50 h.p. motor. The outstanding feature of the mill as originally designed is the absence of wood, the king posts being constructed of cast steel. The mill, when in full operation, is estimated to deal with over 60,000 tons per month, at present only 150 out of the 194 stamps are at work.

The pulp on leaving the mill is lifted by 12-inch Robeson-Davidson centrifugal pumps to the tube mill cone thickeners. The cones are of diaphragm type, fitted with auxiliary cones to arrest any coarse material in the overflow. There are nine tube mills 22 feet by 5 feet 6 inches diameter, driven direct by 100 h.p. motors, the speed reduction being effected by Citroen gearing. The amalgamating tables and extractor boxes are all under the same roof. The amalgamating tables are fixed and dip at an angle of 8 degrees about two-thirds of the total gold recovered being in the form of amalgam. The extractor boxes are divided into six compartments and built of steel. Zinc-lead couple method of precipitation is used.

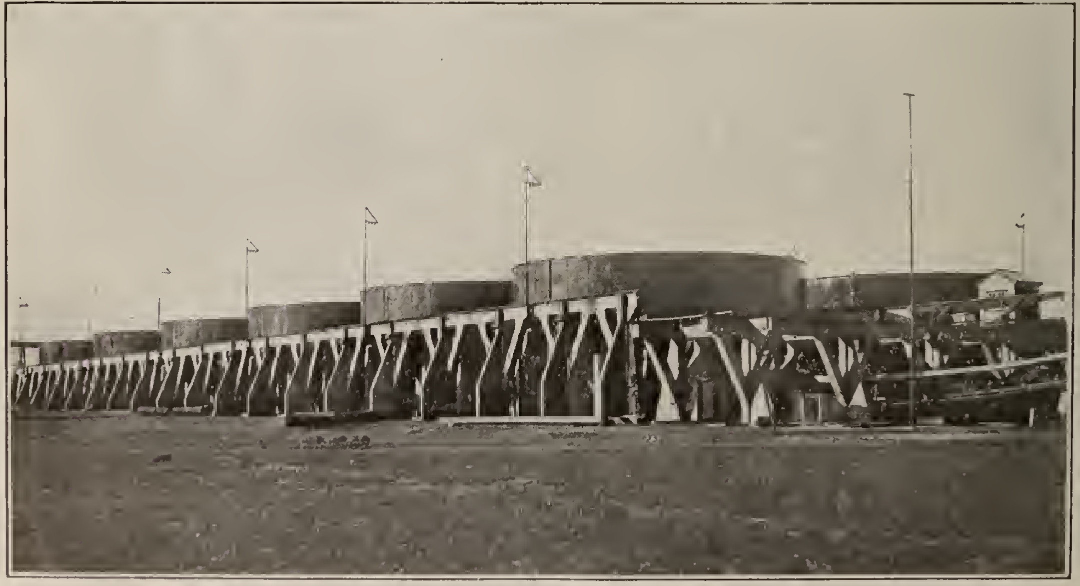


**Nissen Stamps**

After amalgamation Robeson-Davidson pumps are again used to elevate the pulp to the classifiers, the coarse going again to the tube mills and the fines to the sands collector tanks, each of a capacity of 800 tons. The collecting tanks are built of reinforced concrete on similar material for the foundations, the overflow passing into a series of cones where the sand is returned for classification to the tailing pumps, the slimes passing on to the slimes plant. The sand, after draining, is discharged by a Blaisdell excavator and then conveyed by belt to the sands treatment plant consisting of twelve steel tanks on re-inforced concrete foundations. On completion of treatment the sands are discharged by another Blaisdell excavator into trucks and transferred by mechanical haulage in the ordinary way to the residue dump. When milling operations first started the stailings were conveyed to the dump by a Bleichert transporter, consisting of cantilever fitted with conveyors. This method of transporting the tailings to the

**Sand Treatment Plant**

residue dump proved so expensive in use, repairs, and maintenance, that after a few months' use it was abandoned in favour of the common practice of using mechanical haulage. The slimes are treated by the ordinary decantation proecess. There are six collecting



**Sand Collection Plant and Blaisdell Excavator**

tanks each 60 feet in diameter, and eight treatment tanks of 70 feet diameter. There are also two Brown agitator tanks in which the slimes pulp is aerated with compressed air.

The general progress at the City Deep has been far less rapid than was expected on the completion of the mill. The Victoria Falls Power Co. found that it was quite impossible to meet the requirements of the mines of electrical power and compressed air at that time, the City Deep had perforce to instal steam plant as a substitute. This, of course, meant some delay, inconvenience and loss, milling operations starting first with 50 stamps only. Some little trouble was caused by the new ideas introduced in the structure of the mill, but more serious trouble was met with underground, owing to the faulty method of opening the mine and ventilation drawbacks. By far the greatest drawback, however, was the chronic scarcity of native labour with the result that to-day although the native labour scarcity has been almost removed, only 150 stamps out of a total of 194 are at work. It has taken the company two years since milling operations, instead of one year, as expected to reach the dividend-paying stage, owing principally to the scarcity of native labour.

The progress made since the start of milling operations is shown in the following figures:

| Year. | Stamps. | Tons milled. | Revenue. Amount per ton. £ | s. | d. | Expenses. Amount per ton. £ | s. | d. | Profits. Amount per ton. £ | s. | d. |
|---|---|---|---|---|---|---|---|---|---|---|---|
| 1911 | 90 | 349,713 | 537,548 | 30 | 9 | 406,634 | 23 | 3 | 130,914 | 7 | 6 |
| 1912 | 123 | 479,530 | 852,039 | 35 | 6 | 567,158 | 23 | 7 | 292,600 | 12 | 2 |

There is developed sufficient payable ore in the mine to last the mill when fully employed at least four years. With regard to the life of the property all will depend to what extent the milling operations are extended. In the present mining area there must be at least 30,000,000 tons of ore available for the mill sufficient to last the present mill when fully at work, say 30 years, so that if milling operations be considerably extended there ought to be reckoned at least a life of 20 years for present mining area, whilst the additional available mining ground to the south makes the definite calculation of the life of the property impossible.

# DOMINION OF CANADA ORE DRESSING AND METALLURGICAL LABORATORY

The Mines Branch of the Department of Mines has installed at Ottawa a modern well-equipped laboratory for purposes of experimental concentration and metallurgical tests with Canadian ores and minerals.

The following lists of full scale and laboratory size apparatus will convey some idea of the magnitude and latitude of the plant.

## STANDARD SIZE MACHINERY.

### Crushing and Screening.

One Hadfield and Jencks 12 in. × 8 in. Blake crusher.
One Allis-Chalmers 24 in. × 14 in. "Style C" rolls.
One Hardinge 4 ft.—6 in. conical ball mill.
One Ferraris 6 ft.—0 in. screen for coarse sizing.
One Keedy ore sizer, No. 3, for fine sizing.
One Pnplex Callow screen.

### Sampling, Recording, Etc.

Sampling is provided for by two Standard Vezin machines, placed in favourable position to cut out preliminary samples of coarse materials. The fine material will be sampled by an eight unit system of the Flood automatic samplers.

Provision has also been made for hand sampling by means of the Jones riffled samplers.

All water lines serving standard apparatus will be equipped with Keystone water meters, to enable the keeping of accurate records of water consumption.

### Amalgamation and Concentration.

One Allis-Chalmers 5-stamp battery, with 1,250 pound stamps, equipped with a 10-ft. tilting amalgamating table, followed by a Pierce amalgamator. The mortar of this mill may be, if so desired, arranged for inside amalgamation.

Six Callow tanks, 8 feet diam., for de-sliming and settling.

Two Richards pulsator classifiers, launder type.

One Overstrom sand table.

One Deister slime table.

One Richards pulsator two-compartment jig.

One tandem unit Grondal magnetic separator, for wet separation of strongly magnetic minerals.

One Grondal magnetic cobber, with dust collector for dry separation of strongly magnetic minerals.

One Ullrich four pole magnetic separator, for either dry or wet separation of weakly magnetic minerals.

One Huff electrostatic unit, comprising a standard generator and two laboratory size separators.

### Small Scale Apparatus.

One Sturtevant 2 in. × 6 in. laboratory crusher.

One Sturtevant 8 in. × 5 in. laboratory rolls.

One Sturtevant 12 in. × 24 in. laboratory screen.

One Braun planitary pulversizer.

One Abbe six jar pebble mill.

One Gyratory screen (Hoover type), for making dry screen analyses with nested screens.

One Richards combined laboratory pulsator jig and classifier, with glass side.

One Grondal laboratory magnetic separator, for either dry or wet separation of strongly magnetic minerals.

One Wilfley table, 24 in., laboratory size.

One laboratory cyanide plant of 200 pounds capacity, consisting of a Parrel agitator and air pump, with the necessary solution, zinc, and sump tanks.

Two laboratory filter presses.

One complete set of I. M. M. standard screens.

One complete set of Tyler standard screens, after the Rittinger scale.

The installation of an experimental roasting and sintering plant will be undertaken some time during the year.

The plant will be operated free of all charges, including assays necessary for test purposes, on Canadian ores, under the following conditions:

(a) Samples must be bagged and delivered to the plant free of all transportation and unloading charges.

(b) For small scale tests, not less than 200 pounds will be accepted.

For large scale tests, not less than 5 tons will be accepted.

(c) All testing products are to become the property of the Mines Branch, unless otherwise arranged before commencement of tests.

(d) Reports of tests will be incorporated in the publications of the Mines Branch, but single copies will be given to owners of samples when their tests are completed.

Under ordinary conditions tests will be made by the Mines Branch officials, but arrangements may be made be made whereby engineers or other competent persons may supervise their own experiments.

It is expected that the plant will be ready for operation by the first week in July, 1913.

All communications regarding arrangement of tests should be addressed to

EUGENE HAANEL, Ph.D.,
Director Mines Branch,
Dept. of Mines, Ottawa.

# A NOTE ON THE COMPARATIVE EFFICIENCIES OF COMPRESSED AIR VERSUS HYDRAULIC POWER FOR MINING OPERATIONS*

By G. A. Denny.

I have been invited by the Council to contribute a paper to the Institute, which may serve as a type of the communication which the Council specially desires to obtain, namely, short papers dealing with subjects particularly adapted for discussion.

My aim in the following note will be, I believe, perfectly patent to my colleagues. No attempt is made to support by more than generalizations, the statements made, the object being to supply a skeleton around which useful and informing discussion may build a body of opinion and experience, which will be instructive to us all.

In choosing the subject of compressed air transmission, I have especially in mind, that it is one in which we are all interested, and all have more or less costly experience. Morever, it is a branch of our mechanical operations—invaluable and essential though it may be despite its deficiencies,—which offers an excellent target for the critic purposely seeking only its misdeamours, in order to invite discussion in its defence.

In a similar spirit, but from an opposite stand point, the benefits of hydraulic transmission are touched upon, with the intention of provoking critical discussion.

The problems of air compression and transmission are as numerous as they are complex. Pressure, temperature, and volume, have an interchangeability of relationship, which whilst fully covered by theoretical formulae, are most elusive in habit, and unsubmissive to theoretical demands in every day practice.

Our definitions of free air, generally apply to pressures of one atmosphere at sea level, or 14.7 lbs., and 60 deg. temgerature F. But what infinity of variation is there from those bases. Every latitude, every elevation, almost all specific localities, have their own peculiar involutions of volume, temperature and pressure, each new combination giving rise to relationships singular to themselves. Absolute temperatures, must be considered in all cases, whether dealing with free or compressed air, as weight and pressure will vary in accordance with the absolute temperature of the original volume, the latter also suffering variations in conformity with the rise or fall of the absolute temperature. At 30 deg., or 491 deg. absolute, a cubic foot of dry air at sea level and average atmospheric pressure weighs .0811 of a lb., and the volume of 1 lb. at this temperature and pressure, is 12.336 cubic feet. At 90 deg. F.—absolute 551 deg.—a cubic foot weighs .0722 lbs., with a volume for 1 lb. of 13.853 cubic feet. At 200 deg.—absolute 661 deg.—a cubic foot weighs .0602 lbs., with a volume of 16.907 cubic feet.

The relationships of temperature, pressure and volume have been succintly stated as under:

1. The absolute pressure of air, varies inversely as the volume, when the temperature is constant.
2. The absolute pressure varies directly as the absolute temperature, when the volume is constant.
3. The volume varies as the absolute temperature, when the pressure is constant.
4. The product of the absolute pressure and the volume is proportional to the absolute temperature.

*From the Bulletin of the Mexican Institute of Mining and Metallurgy.

When air is compressed, an increase of temperature takes but not proportionate to the pressure, nor will air which is taken into the cylinder at zero, have a temperature increment similar to air which is taken in at 100 deg. At two atmospheres gauge pressure, for instance, air of an initial temperature of zero, will have risen to 170 deg., whilst air of an initial temperature of 100 deg. will have risen at the same gauge pressure to 320 deg. In the higher pressures, the rate of temperature increase is much lower. For instance, air of an initial temperature of 100 deg. will only rise about 20 deg. between gauge pressures of 21 and 23 atmospheres.

The importance of the question of original temperature of the free air, cannot be overestimated, since that volume of free air which we take into the cylinder, is in the last resort the unit we have to count upon for work. If the air is so heated at the moment compression begins, that its volume is increased by say 20 per cent., we are actually reducing the capacity of our machine—from a basis of cool air—to that degree, and have to exert as much power for the compression of an 80 per cent. cylinder charge, as would be required for an 100 per cent. charge of cooler air.

Even when every precaution has been taken to provide the coolest and cleanest supply of air available, to the compressor, we still have the heated condition of the air cylinder itself to contend against, which causes an immediate rise in the temperature of the entering air, reduces the volume, and deprives us of a fixed, but unascertainable amount of eventual energy. No determination has ever been made of the exact rise in temperature of the entering air, in any given instance, nor does it appear likely from the nature of the case, that it will ever be accurately fixed, as the indicator gives us no information on the point.

The safest way to minimize losses in this direction is to lead the air into the cylinders from cool places, in channels or conductors of wood or concrete, or other material which is a bad heat conductor or radiator.

Having the air in the cylinder, we now proceed to reduce its volume and increase its pressure. If this could be done without creating heat, the air would conform to the ordinary law of gases, namely, that its volume would vary inversely to the pressure, and a diagram of the operation in the cylinder would give us an isothermal compression line. In that case (if it were possible), assuming the air to be originally at one atmosphere pressure, sea level, and 60 deg. Fah., and that we have compressed it to 80 lbs. gauge pressure, the original volume of air taken at 1, would be reduced to .1552, and the mean pressure per stroke would be 27.33 lbs.

It is well to keep these ideal conditions in mind, in order to see how far short of them our actual practice falls.

In the same conditions as above, and assuming no air cooling, the volume of air after compression is .267 of the original unit, and the mean pressure per stroke 36.6 lbs. That is to say, in practice, where no cooling arrangements exist, we require 34 per cent. more power for the air compression, because the volume of air has been increased by heat. In the best practice, with all the cooling arrangements possible, or practicable, a result somewhere between the two figures is attainable. The methods of air cooling that have been tried are three, namely:

1. Water jacketing of the cylinders.
2. Water spraying in the compressing cylinder.
3. Cooling in a special apparatus between the compression stages.

As we are treating at the moment of only single stage compression, the first two are all to which we need refer.

Of the two systems under notice, that of water jacketing, is the one almost universally adopted. In this system, however, the cooling effect is at best, very ineffective, since the inner surface of the cylinder can only be slightly cooled, and can, therefore, only effect a film of adjacent air, leaving the large bulk of air, in the central portion of the cylinder almost untouched. For this reason cylinders of small diameter must allow of better cooling than large cylinders, but other mechanical considerations will out weigh this advantage, where a large output is required. The practice of water spraying in the compressing cylinder has almost been abandoned. The practical objections to it are:

(a) That it produces very moist air, which freezes in expanding, and blocks the exhaust passages of pumps, etc., with ice;

(b) That it necessitates very large clearances in the cylinders and restricts operations to comparatively low piston speeds;

(c) That it gives rise to serious difficulties in the lubrication of the cylinder; increases friction; induces excessive cylinder wear, and reduces efficiency.

If it were possible to utilize the heated air immediately, without loss in volume due to cooling, we should not have to deplore the large power losses represented by the difference between isothermal and adiabatic compression. But in practice the air after compression is discharged into receivers and pipe lines, and returns more or less to its original temperature, with a corresponding shrinkage in bulk, and with lessened energy possibilities. Attempts to restore in part the lost energy due to volume shrinkage, are made by reheating the air, near the point at which it is to be used, but it may be said in general, that no reheating apparatus finds a place in mining installations, and therefore no recovery of the loss due to adiabatic compression is made.

It is perhaps well to emphasize the fact that an air compressor has two quite separate and distinct functions to perform, namely:

(a) That of increasing the pressure of the air from a pre-existing to some determined pressure;

(b) That of discharging the air of a determined pressure into the mains.

We have seen that the admission of the maximum volume of cooled air into the cylinder is the first desideratum in the process of increasing pressure, since the capacity of the machine is reduced, and power is wasted in proportion to the temperature of the air above a certain practicable minimum.

Similarly with the discharge. As the volume of air, owing, firstly, to the admission of warm air, and, secondly, to the heat generated by the compression, will have greatly increased, the power required for its discharge will be proportionate to the bulk of air discharged. If at the moment compression begins, the air has a temperature of 60 deg. and if it were compressed, insolthermally, or .3144 if adiabatically compressed, and the temperature in the latter case would be 375 deg. In this instance, the volume of air after compression has a bulk 60 per cent. greater than it would have had if the air had been kept down to a temperature of 60 deg. Again if the air at the moment of compression had a temperature of 80 deg., or 20 deg higher than before, and were compressed to 80 lbs. gauge, its final volume would be .1552 isothermal, or 267 adiabatic, and the temperature in the latter case would be 432 deg. Here the air after compression has a bulk of over 71 per cent. greater than it would have had, could the isothermal conditions have been realized. In order to discharge the increased bulk of air, therefore, we require over 71 per cent. more power than would be necessary if the temperature of the air could be retained at 80 deg. F. throughout the operation.

The horse power required to compress 1 cub. foot of free air to a pressure of 80 lbs. adiabatically is .184 of a h.p., and the power necessary for the discharge of 1 cubic foot of the compressed air into the receiver, is 1.85 h.p.

The important practical considerations in the figures just given are that:

(a) The air is not in a condition to be applied to our purposes, until we hace expended a considerable amount of power in the reduction of its volume.

(b) The power required for the discharge of the air is to a large extent wasted, because in the conditions we have taken, we must discharge a bulk of 1.71 units of heated air, which, after cooling, becomes only one unit available for power.

We may examine, further, in the light of the foregoing statements into the pneumatic efficiency of the compressor.

If a normal diagram from a single stage compressing cylinder be examined, it will be seen that it is exactly the opposite of a steam cylinder diagram; steam admission being represented by air delivery; steam expansion by air compression; and steam compression by the air re-expansion line. An interpretation of a normal diagram from a single stage machine compressing free air at 60 deg., to 80 lbs. gauge, will show that the work done may be divided as under:

(a) Work done in raising air pressure;

(b) Work done in excess due to heat;

(c) Work done in expelling compressed air to the receiver.

These operations may be expressed numerically as under, having reference to one stroke of the piston:

1. .734 of the stroke used, at a mean effective pressure of 20.5 lbs. for bringing the air from atmospheric pressure to 80 lbs. gauge, or .734 x 20.5 equals 23.911 stroke pressure units.

2. The excess bulk due to heat is 71.4 per cent., and the volume of compressed air at 60 deg. is .1552 of the original volume. Therefore the excess work done due to heat is .714 of .1552 or .1108 of the stroke, at the delivery pressure of 80 lbs., or .1108 x 80 equals 8.864 stroke pressure units.

3. The part of the stroke which furnishes us with power in the receiver, that is for our purposes, the really useful portion of the stroke, is that proportion of it which is required to expel the volume which the compressed air will occupy when cooled, namely, .1552 stroke working against a pressure of 80 lbs. or .1552x80 equals 12.416 stroke pressure units.

We thus have for the total stroke an aggregate of 36.327 stroke pressure units.

The only portion, however, as before stated which provides us with air at working pressure is that referring to the discharge, namely, 12.416 units, the remainder being losses in bringing the air up to pressure, and in heat. That is to say, we get a useful result only from 34 per cent. of the power put into the work, and 66 per cent. may be reckoned as loss. Apart from, and in addition to this loss, are the losses inseparable from the machine, as such. To begin with, the volume of air compressed is never the full contents of the cylinder, since there is clearance to be reckoned with, and lateness in reaching full atmospheric pressure, on the admission side. The mechanical losses may be put down at 10 per cent. for the friction of the machine, 10 per cent. for losses due to increased temperature of the air after admission, 10 per cent. for losses due to clearance, leakage, valve resistance, etc. This leaves 70 per cent. only available for air compression, and of this available amount of power, we have seen that only 34 per cent. does useful work. Then 34 per cent. of 70 per cent., or 23.8 per cent. is all the useful effect we get, expressed in terms of air delivered to the receiver.

We have so far dealt with figures relating to single stage compression, and the question now arises, as to what extent the losses in single stage practice will be minimized by double stage compression.

The sole object of double stage compression is, of course, the avoidance to the greatest extent practicable, of the heat losses, by cooling the first stage air, before it enters the second stage cylinders.

Below are the figures so far as they relate to temperatures, of an actual test. The test was made upon a horizontal cross compound two-stage compressor, with suction air valves mechanically operated, delivery valves of automatic design to close in equilibrium, air cylinders water jacketed both on barrel and ends, intercooler between the cylinders.

| | |
|---|---|
| Temperature of air at instake .......... | 81.6 F. |
| Temperature of air low pressure delivery. | 252.1 F. |
| Temperature of air intercooler ........... | 148.2 F. |
| Temperature of air high pressure delivery. | 262.4 F. |
| Pressure of air in intercooler ........... | 34 lbs. |
| Pressure of air in receiver .............. | 91.7 lbs. |

It is interesting to note the effect of the jacket cooling on the air of the low pressure delivery. The final temperature of the air, without any jacketing would be 310 deg. F. therefore the jacketing has lowered the temperature only 58 deg. and has affected the volume of air, therefore, to a very limited extent.

If isothermally compressed, the volume of air would be over 30 per cent. less than the adiabatic volume, showing that the water jacketing in this case has given far from an effieient result.

Turning now to the intercooler, we find that it lowered the temperature of the air by 104 deg., but still the air had a temperature of 148.2 deg. or 66.6 higher than the original intake, and the capacity of the delivery cylinder would be prejudiced and its useless power increased proportionately to the excess volume occupied by the heated air. The complete cooling which is often claimed in the intercooler, was therefore far from being realized in this instance.

It is still a matter of opinion amongst many of the best informed engineers on this subject, whether for ordinary working pressures, say up to 80 lbs. gauge, there is any advantage in double stage practice. In a booklet published by a well known maker of compressors, the following statement is made.

"The very processes of compounding may too easily lead into mechanical difficulties which in the aggregate, may not only counterbalance the gain by compounding, but may actually swing the balance in the other direction, and result in a machine of lower efficiency, as compared to the single stage machine of the best class."

Following upon the losses incident to the compression and delivery of compressed air to the receiver, we have the losses in the pipe lines and in the machines which utilize the air for power purposes. Theoretically the losses in air mains should be very low, given perfect conditions, and not great distance, but in ordinary mining practice, there is no question that they are frequently very high. A test made under my own supervision in a large South-African mine, showed that the receiver and pipe line, losses amounted to 11.5 per cent. of the indicated horse power of the engine. This loss is, of course, made up mainly of two components, friction and leakage, in what proportions could not be determined. It is probable that 10 per cent. would be a fair figure to adopt for leakage and friction in the ordinary mine installation.

We have now to consider for a moment what efficiencies are obtained from compressed air in ordinary mine usage. Rock drilling and pumping are perhaps the principal applications of compressed air power in mines, though it is used for a variety of other operations such as hoisting, signalling, ventilating, etc.

Considered as an engine, the ordinary rock drill is not an efficient machine, since it uses air at full pressure throughout the piston stroke. The average drill develops about 1.5 h.p. In order to obtain this power, it has been proved by test that the steam engine working the air compressor must develop anything from 25 to 32 h. p., so that the overall efficiency of the system is terms of power at the rock drill bit is in the neighbourhood of, say, 5 per cent. It seems incredible, that rock drilling operations are so inefficient, but it is nevertheless true, that the above rate is probably representative of the large majority of mine installations.

Pumping by compresser air is largely resorted to in mines because of its convenience, or expediency, or both. On a test made under my own supervision on a large mine, in which all the auxiliary pumping was done by compressed air, using 7 pumps, the efficiency of the pumps as a whole, on the original power put into the compression, worked out at between 9 and 10 per cent. The pumps used were the ordinary steam pump, in which all losses due to clearance and unsuitability for the pressure used, were greatly exaggerated. Still they represent average practice in this respect, and the losses, similarly to those occurring in rock drilling, are so high as to seem almost incredible.

I have said enough, I think, about the losses incident to the generation and use of compressed air, to stir up a vigorous defence amongst its champions, from which we must all benefit.

In contradistinction to the losses involved in an air compressing and transmission system in its application to rock drilling I will now state very briefly the features and advantages of hydraulic transmission for a similar application.

The outstanding difference between air and water from the point of view of power development and transmission is, that water is non-elastic.

Unimportant as this apparently simple difference is on first view, it will be found on closer examination to describe practical immunity from nearly all the heavy losses incident to air transmission and compression, as under:

1.—There is no initial capacity loss due to increased temperature after admission to the working cylinder.

2.—There is no complicated and expensive mechanism required in developing power, whether the head be gained by artificial or natural means, and there are no large friction losses.

3.—There are no heat losses.

4.—No power is required for the preliminary compression, and in consequence, instead of suffering the tremendous losses incident to the process of bringing the water up to working pressure, all the power is utilized in discharging it into the pressure mains. The importance of this is better appreciated, when we state that one unit volume of water at 1,000 lbs. pressure allowing 5% for cylinder and other losses, would transmit 95,000 volume units of pressure, whilst one unit volume of air compressed to 80 lbs. gauge, owing to the small percentage of the stroke available for delivery to the mains, would not transmit to exceed say 2,000 volume units of equal pressure.

5.—There are no clearance losses.

6—With extremely simple mechanism very high working pressures from 500 to 1,000 lbs. and upwards per square inch may be developed.

7.—At working pressures such as mentioned in the previous paragraph, the transmission losses are negligeable, and the volume of water required, and the hydraulic mains are very small.

The overall efficiency of a hydraulic system, in terms of power delivered to the hydraulic drills would not be less than 80%. The efficiency of the drill would range, according to the type employed from say 60% to 80%. Therefore the over all efficiency of the entire system would not be less probably than 50%.

On the same basis, the efficiency of a steam driven compressed air system will not exceed 6%.

Mexico is a country of water powers, and potential hydraulic transmission projects. In view of the great advantages offered by hydraulic transmission and and hydraulic drills, it is greatly to the interest of the mining community, to make most careful enquiry into the possibilities of adopting it.

Where natural fall is not available for pressure purposes, a pump of comparatively simple and efficient type is all that is required to develop any working pressure desired.

---

# GRANBY CO'S. OPERATIONS

The Boston Commercial has published the following information concerning the operations of the Granby Consolidated Mining, Smelting and Power Co., Ltd.

The Granby Consolidated Co. produced 5,539,419 lbs. of copper during the first quarter of the current year and made a net profit of about $194,000. The production by months compares as follows:—

| | Copper. lbs. | Silver. oz. | Gold oz. |
|---|---|---|---|
| January. . . . . . . . . | 1,792,245 | 23,952 | |
| February. . . . . . . . . | 1,779,212 | 24,645 | 3,430 |
| March. . . . . . . . . . . . | 1,967,962 | 28,352 | 4,211 |
| Total for 3 months. | 5,539,419 | 76,949 | 10,907 |

It is understood that the grade of the ore at the Phœnix property improved somewhat during the past month or two. This has offset to some extent the lower prices received for copper and the slightly increased mining costs resulting from interrupted operations in February, chiefly due to inclement weather.

The March run of the smeltery was a record breaker with the full battery of eight furnaces operating for 31 days, as compared with a 20-day run in the preceding month.

Construction work at the Hidden Creek property is well under way, with foundations being laid for the various buildings.

Mr. William H. Nichols, President of the Granby Co., issues the following report to the stockholders:—

"Since the last quarterly report, January 22, 1913, the forward policy of the company recommended by the directors has been adopted by the shareholders and the company is in position to avail itself of any opportunities which conservative judgment may dictate ant at the same time to push to completion the work already undertaken, and resume payment of a moderate dividend out of the profits from current operations.

"At Anyox the work laid out has steadily progressed without any disappointment to, although some construction work was somewhat hampered by the winter snows which have been quite unusual for that region. Our engineers, however, still expect to have the works in condition to operate in November and December of this year.

"The operations of the Phœnix mines and Grand Forks smeltery for the month of March showed a profit of $87,770, and for the nine expired months of the fiscal year, to March 31, $990,255. The yield of metals has been fully maintained, and the cost of copper for March slightly reduced, but current profits for a portion of this period were interfered with by the decline in the price of copper. All figures are now based on copper at 14½ cents, and on March 31 we had on hand 1,935 tons taken in at that price.

"Reports from the development work of the old properties indicate that ore reserves there have been fully maintained."

---

Mr. Alex. H. Smith is expected to reach Toronto early in June.

Mr. A. A. Hassam is examining the mine of the Boston and Goldenville Gold Mining Company at Shiers Point, Nova Scotia.

# ANNUAL REPORT OF THE BRITISH COLUMBIA CO., LTD.

The annual report of The British Columbia Co., Ltd., for the fiscal year ended December 31, 1912, follows:—

### President's Report.

Mr. Newman Erb, President of the company, reported as under:

"The report of the Acting General Manager, with Auditors' Certified Balance Sheet, and Profit and Loss Account, for the fiscal year ended December 31, 1912, is herewith respectfully submitted by your Board of Directors.

"The results of operations include the month of December, 1912, by reason of a change made in the fiscal year, as a matter of convenience, to correspond with the calendar year, and the reports therefore cover a period of thirteen months.

"The quantity of ore treated at the company's smeltery was 740,589 tons, of which 443,022 tons was derived from the company's mines, the remainder having been custom ore. Metals were: Fine copper, 11,146,-811 lb.; silver, 142,025 oz.; gold, 25,863 oz. The proceeds of these metals amounted to $2,483,663.96.

"The net results of operations were $425,985.40, being the largest in the history of the company. From these profits there were paid during the period covered by the reports, two dividends, Nos. 4 and 5, aggregating $177,512.70.

"During the fiscal year the company paid on account of new properties and in their exploration and development, $229,489.46. Because of the great importance of supplementing the ore reserves of your company, as has been referred to in previous reports, and in furtherance of the the policy adopted, options, through bonds, were taken upon a number of properties which your operating officials believed were of sufficient promise to justify exploratory work. These consisted of the following, all in British Columbia, and were considered properly tributary to the company's smeltery:

1. Ada B. group, in Princess camp.
2. Silver Dollar claim, in Princess camp.
3. Annie L. claim, in Princess camp.
4. Princess Maud claim, in Princess camp.
5. Red Eagle claim, in Princess camp.
6. Triangle Fractional claim, in Princess camp.
7. Eureka group, near Nelson.
8. Queen Victoria group, near Nelson.
9. L. H. group, near Silverton.
10. Riverside group, on North Fork of Kettle river.
11. Copper Mountain district.
12. Greyhound mine, Deadwood camp.

"The development on Nos. 1-9 of the foregoing, on which $57,918.39 was expended, proved to be so encouraging that the company concluded to acquire them and made payments, on account of the option bonds, amounting to $21,000. On the last two very extensive explorations were conducted, but further development was, for the time being, abandoned. The company, however, acquired one-half interest in the Frisco and thirteen other claims in the Voigt camp, on Copper mountain, and subsequently acquired a mortgage which covered the other half interest on these latter claims, which are all embraced in the Copper Mountain district.

"Indications are that in the Princess camp the company will develop a copper mine of considerable extent and value, and the work still in progress is intended to determine the extent of ore-bodies and the method of their treatment. It appears the products of these mines can be successfully concentrated and, if so, profitably transported to be treated at the company's smeltery. The exploration work under way at the close of the fiscal year will be continued.

"During the year under review the company has added to its holdings of New Dominion Copper Co. securities bonds of the par value of $237,675, which cost $122,249.25.

"Operations for the fiscal year were on the whole encouraging and satisfactory. With the opening of the new mines and the completion of the plans now under way for supplementing the ore reserves, which appear to be assured, it is believed stability will be given to the company for the future.

"The management desires to express its obligation to the operating force, and to the intelligent co-operation, fidelity and zeal of its officers, for the results obtained during the year."

### Acting General Manager's Report.

Mr. Frederick Keffer, Acting General Manager, reported as follows:—

For the fiscal year of thirteen months, ended December 31, 1912, the following review of the company's operations is submitted:

"Shipments of ore were made from the company's mines, as under:—

| | Tons. |
|---|---|
| Mother Lode | 410,688 |
| Wellington group | 9,935 |
| Lone Star and Washington | 2,101 |
| Napoleon | 17,118 |
| Queen Victoria | 1,080 |
| Total | 440.920 |

"**Mother Lode Mine.**—The transverse stope method of mining has been followed throughout the year, and has proved most successful in extracting the maximum quantity of ore at a minimum of cost. The tonnage shipped was the greatest for any one year in the history of the mine, and the cost of crushed ore, f.o.b, cars. at the mine has been the lowest, namely, 56.58 cents per ton. The drilling of new ground has been kept well ahead of requirements, there having been at the close of the year 5,000 holes, aggregating 65,000 lineal feet, in readiness for blasting.

"The ore reserves have not been materially increased during the year. The average grade of ore mined was below the normal grade of former years.

"The mining plant has been maintained in good condition, and the large quantity of ore has been extracted without serious accidents to either men or machinery.

**Wellington Camp Group.**—The ore that had been developed here was mined out during the seven months in the earlier part of the year, and in June the mine was closed for the time being. There is a large area of unprospected territory included within the company's holdings in this camp, but owing to extensive prospecting in other localities it was thought best to postpone further operations at the Wellington group until a later period.

"**Lone Star and Washington.**—This mine was operated in June, July and August only as, on account of the refractory nature of the ore, but little of it could be smelted directly. Working tests on large lots of the ore, using ordinary water concentration method, did not prove sufficiently successful to warrant the erection of a concentration plant. We are, however, making tests on other lines, which so far have proved satisfactory, and lead to the expectation that the problem of successful concentration and elimination of the refractory constituents of the ore will shortly be solved. The 300,000 tons of developed ore in this property, comprised within less than seven per cent. of its area, together with the comparatively high grade of the ore, make the ultimate solution of the problem of treatment a most important matter.

"**Napoleon.**—The 17,118 tons of sulphide flux shipped from the Napoleon mine during the year was of better grade, both as to gold and sulphur contains, than that for a number of earlier years. Mining and tramway costs were reduced to an average of $1.588 per ton of ore. The ore shipped was offset by new ore developed, leaving the ore reserves unchanged. These reserves are sufficient to serve all needs for many years to come. The machinery, plant and aerial tramway have been maintained in good condition.

"Through delays in receipt of machinery and by reason of further alterations found necessary at the Napoleon mill, it was late in September before all the problems relating to the treatment of the ore were finally and successfully solved. The quantity of ore milled was 6,483 tons. On account of the increased expense of mining and milling the oxide are in the winter season, when in the open quarry work it becomes mixed with snow and freezes into masses not readily handled, it was decided to close the mill until the spring of 1913, after which a steady and successful run should be had.

"**Queen Victoria.**—This property, which is situated nine miles west from Nelson, B.C., was purchased in November, 1912. The ore in it is an altered limestone similar in self-fluxing properties to the Boundary district ores, but it contains a higher percentage of copper. The mine is equipped with an electrically-driven compressor plant, and is connected with the Canadian Pacific Railway by an serial tramway.

"The months of November and December were occupied mainly in getting the mine into general working shape, and in opening new ground for stoping. In December, 1,080 tons of ore was shipped.

"**Smeltery.**—The smeltery at Greenwood was operated steadily throughout the year and smelted a larger quantity of ore than during any similar period in its history. During the first two and a half months, until a sufficient supply of coke was secured for the entire plant, only two furnaces were operated. The total quantity of ore smelted during the thirteen months of the fiscal year was 740,589 tons, as compared with a total of 608,945 tons for the twelve months of the fiscal year ended November 30, 1911. The sources of the material smelted were:

| | Tons. |
|---|---|
| From B.C. Copper Co.'s mines ...... | 443,022 |
| Custom ores ...................... | 284,575 |
| Converter slags .................. | 12,992 |
| Total ........................ | 740,589 |

"The quantity of coke consumed was 103,154 tons.

"The converter slags included:

| | |
|---|---|
| B.C. Copper Co.'s ores ............. | 914 |
| Custom ores ...................... | 4,104 |
| Clay ............................ | 1,205 |
| Total ........................ | 6,223 |

"There was produced 11,250,140 lbs. of blister copper, containing:

| | |
|---|---|
| Gold .................... | 25,862,681 oz. |
| Silver .................. | 142,025.06 oz. |
| Copper ................ | 11,0148,811.00 lbs. |

"No material additions were made to plant during the year, the machinery as a whole having been maintained in its normal condition.

"It is planned to use basic instead of acid lining for the converters, should this be found practicable without considerable additions to the plant. Through decreased cost for clay and elimination of labour in relining converters, it is probable that a decided reduction in the cost of converting can be effected.

"**Prospecting Operations.**—During the year twenty-three groups of mining claims in British Columbia or adjacent parts of the United States are examined by our engineers. This work resulted in the bonding of the Eureka group, near Nelson, B.C., and of a group of mineral claims on Copper mountain, near Princeton, B.C., known collectively as the Princess group. On these two properties exploration is being vigorously pushed by both handwork and diamond-drilling, with generally favourable results to date. Much exploration work was also done in Voigt's camp, on Copper mountain, with fairly successful results. The bond on the group in Voigt's camp was allowed to lapse, but negotiations are now in progress for renewal. Among the groups examined are three others of much promise; it is planned to explore these during the coming season.

"**Operating Costs.**—The yield i ncopper, gold, and silver for the past year was less per ton of ore than for any other year in the history of the smelting works; the costs per ton for ore-handling, etc., were lower than for any other year. On account of the low yield of metals, the cost of producing copper per pound was 12.85 cents, notwithstanding the very low handling costs.

"The following table gives a comparison of the principal items for the last five years:

| | 1908 | 1909. | 1910. | 1911 | 1912. |
|---|---|---|---|---|---|
| Yield of copper per ton of B.C. Copper Co.'s copper-bearing ores ................................ | 17.8 lb. | 17.7 lb. | 18.0 lb. | 16.4 lb. | 13.6 lb. |
| Yield of gold and silver per ton of B.C. Copper Co.'s Ores ...................................... | $0.985 | $1.03 | $1.23 | $1.133 | $0.762 |
| Average price realized for copper ................. | 0.13504 | 0.1308 | 0.12778 | 0.1233 | 0.16664 |
| Costs of producing, refining and marketing per pound of fine copper, after crediting expediture with value of gold and silver contents of ore .......... | 0.09996 | 0.09829 | 0.09048 | 0.11635 | 0.12855 |
| Costs of handling ore per ton, including all charges from ore in place to sale of the contained metals.. | 2.632 | 2.683 | 2.730 | 2.882 | 2.4596 |

"In concluding this report the writer wishes to bear testimony to the uniformly loyal support and excellent work of all those in charge of the various departments of the company, whose collective work has enabled the company to attain the results set forth in the statement of the auditors."

**Profit and Loss Account.**

"For thirteen months ended December 31, 1912:

| | | |
|---|---|---|
| "To operating disbursements— | | |
| Mining, smelting, freight, refining and selling charges, general office and administration expenses, maintenance of plant and equipment | $1,570,205.16 | |
| To custom ore purchased | 495,087.12 | |
| By proceeds of metal shipments, including those unsettled for at December 31, 1912 | | $2,483,663.96 |
| By miscellaneous earnings | | 7,613.72 |
| To balance carried down | 425,985.40 | |
| | $2,491,277.68 | $2,491,277.68 |
| By balance brought down | | $425,985.40 |
| By balance at November 30, 1911 | | 717,264.11 |
| To dividends Nos. 4 and 5 | $177,512.70 | |
| To balance carried to Balance Sheet | 965,736.81 | |
| | $1,143,249.51 | $1,143,249.51 |

**BALANCE SHEET AS AT DECEMBER 31, 1912.**

**Liabilities.**

| | | | |
|---|---|---|---|
| Capital Stock— | | | |
| Authorized $3,000,000 in 600,000 shares of $5 each. | | | |
| Issued | 596,709 shares of $5 each. | | |
| Less in Treasury | 5,000 shares of $5 each. | | |
| | 591,709 | | $2,958,545.00 |
| Sundry Creditors— | | | |

# THE OCCURRENCE OF PYRITES IN CANADA*

(Continued from April 15th issue.)

### NORTHERN ONTARIO OCCURRENCES.

**Northland Pyrites Mine.**—This property is located on the shore of James Lake, about three-quarters of a mile west of the Temiskaming and Northern Ontario Railway at the 83rd mile post. The discovery was made in 1903, but active development was not commenced until December, 1906.

The main shaft has a depth of 300 feet, with levels at 100, 175 and 275 feet. A winze was sunk from the second level, 75 feet north of the shaft, a depth of 100 feet, a drift running to the shaft, and then a raise was put up to connect with the shaft at the second level. Some of the ore north of the shaft has been removed by open cut workings, and a considerable amount of ore has also been stoped out on the second and third levels.

The main shaft on the deposit dips with the schist at an angle of about 70 degrees to the west. The lens-shaped ore body lies in a soft green schist about 100 feet east of the contact with a grey hornblende granite. The only impurity in the ore consists of small veinlets of quartz and massive pyrrhotite on each wall of the lenses. Occasionally, pyrrhotite is also finely disseminated through the pyrite. The ore breaks nicely, making very little fines in the course of mining

*See page 316 for General Map.

The ore is usually mined by underhand stoping. It is hoisted to the shaft house, where it is broken and cobbed. It is then dumped directly from the storage bin to the cars, a siding from the Temiskaming and Northern Ontario Railway having been built to pass under the ore bin. The greater part of the ore was shipped to Buffalo, N.Y.

The mine is equipped with two 100 h.p. boilers, a 12-drill air compressor, and a hoist.

The property is at present closed down.

In 1909, Mr. L. Hanna was manager. The head office of the operating company is at London, Ontario, and Mr. John Smallman is treasurer.

### WESTERN ONTARIO OCCURRENCES.

**Helen Iron Mine Pyrites Deposits.**—Located in the Michipicoten mining division, about 15 miles northeast of Michipicoten harbour, Lake Superior.

The Helen iron mine has been fully described in various reports of the Ontario Bureau of Mines.*. Underground working has revealed the existence of pyrites in large quantities. The pyrite and hematite deposits lie in a roughly elliptical rock-rimmed amphitheatre bounded on the east by a steep hill of iron carbonate, on the north by cherty carbonate and quartz porphyry schists, on the south by quartz-porphyry schist, and on the west by pyritous and cherty iron carbonates. The rock structures are almost vertical.

The Helen iron mine occupies the eastern end of a great pit-like depression. The ore body, as shown by the plans of the several levels, is elliptical in outline with an east and west axis about 500 feet in length, and a width of about 300 feet.

Lenses of pyrite occur throughout the hematite deposit, and the sulphide also occurs to the east, north and west of the hematite ore body. The pyrite consists almost entirely of granular ore. Lumps of hard ore are occasionally found, but the greater portion of the sulphide is in a fine granular condition resembling very clean concentrates. Occasionally, small veins of a clear, white quartz sand occur. Samples of ore will assay over 50 per cent. sulphur. Mine shipments will grade about 42 per cent. or better, dependent upon the amount of hematite that may become mixed with the ore.

The pyrite in the lenses or pockets, being closely confined by the hematite and of a saccharoidal structure, flows readily, like hot dry sand, wherever the pressure is relieved. Therefore, if an opening happens to be made in one of the lenses, it is necessary to take prompt measures to prevent the flow and to regulate it, if necessary. Special timbering is necessary, and even then the pressure is so great that opening into the pyrite can only be maintained with difficulty and for a short time.

Arrangements are being made to maintain a steady annual output of pyrites from this mine, which will probably be one of the largest pyrite producers in Ontario.

**Conmee Township.**—Thunder Bay district, Lot B, Concession V. Some work has been done on a deposit which lies on this lot about a quarter of a mile west of Bridge 31A, on the Canadian Northern Railway, some distance below Mokoman Station.

**Tip-Top Copper Mine.**—This property is situated 9 miles by trail southwest of the Canadian Northrn Railway at Kashaboiwe station. The main shaft is 200 feet deep, dipping 70 degrees to the north, and four levels, 50 feet apart, have been driven. The following is a synopsis of the work done in the various levels:

1st level. Drift to east. 80 feet in length.
1st level. Drift to west. 40 feet in length.
2nd level. Drift to east. 70 feet in length.
2nd level. Drift to west. 40 feet in length.
3rd level. Drift to east. 60 feet in length.
3rd level. Drift to west. 40 feet in length.
4th level. Drift to east. 65 feet in length.

Cross cuts:
1st level to the south. 60 feet in length.
1st level to the north. 140 feet in length.
4th level to the north. 130 feet in length.

Stopes:
1st level east. 40 feet long, 25 feet high, 8 feet wide.
1st level west. 30 feet long, 15 feet high, 10 feet wide.
2nd level east. 40 feet long, 10 feet high, 10 feet wide.
2nd level west. 30 feet long, 10 feet high, 8 feet wide.

Shaft No. 2, about 600 feet north of east from No. 1, is 50 feet deep.

Shaft No. 3, about 500 feet east from No. 2, is 20 feet deep.

The plant consists of 2 boilers one 70 h.p. return tubular, and one 30 h.p. marine; one hoist, cylinders 6 in. $\times$ 8 in., one Ingersoll-Sergeant 4-drill air compressor.

The associated rocks, according to Miller,† are a series of talc and green schists. Diabase occurs as a dyke rock and also felsite. The ore consists of copper pyrites, pyrrhotite and iron pyrites. It carries values in gold in addition to the copper.

The Tip-Top is essentially a copper prospect. Massive pyritic lenses in the mine would run upward of 40 per cent. sulphur, but there are extensive associated bodies of leaner and very highly siliceous ore.

**Steep Rock Lake Deposits.**—The depsits in the vicinity of this lake were very thoroughly prospected for iron ore. They lie north from Atikokan station on the Canadian Northern Railway.

Three-quarters of a mile west from the shore of the lake, the Mackenzie and Mann locations AL 461 and 462 have been prospected by four diamond drill holes. These are said t ohave disclosed a deposit of pyrites, but details are not available. The country rock on the surface is interbanded silica and highly altered green schist.

A very large deposit of iron pyrites has been uncovered at the southern extremity of Straw Hat lake. This is reached by a trail to the westward from the southern part of the eastern arm of Steep Rock lake. The work done comprises trenching, test pitting, and 4 diamond drill holes on locations 857 X and 858 X. The south trench shows a width of pyrite of over 140 feet, the eastern 60 feet of which would be quite high grade at shallow depth, as the only impurity was gossan. The ore showed unequal banding and nodular weathering. The astern portion of the ore shown in the trench is somewhat siliceous, and would not run more than 38 per cent.-40 per cent. sulphur. A test pit 100 yards to the north near the camps, shows very fair pyrites under a heavy capping of limonite and hematite. The hill, on which the south trench is located, is 30 feet high, and the whole gully to the west appears to be underlain with pyrite. Diamond drilling disclosed the

---

*O. B. M. Reports for 1898, 1901, 1902, 1903, 1904, 1905.

†Ontario Bureau of Mines, 1903, p. 102.

pyrite in the form of a vast crescent, between the horns of which lies a deposit of hematite, an occurrence resembling very much that of the Helen iron mine.

The country rock to the west is an eruptive greenstone, and to the east it is a green chist. These, along the trail to Steep Rock lake, show at times a curious ellipsoidal weathering.

The deposits is 4 miles level draw from the Canadian Northern Railway to the southwest.

**Vermilion Pyrites Mine.**—This property, formerly the Vermilion Pyrites mine, and still earlier the Michie Pyrite mine, is now operated by the Northern Pyrites Company, 25 Broad Street, New York. The mining locations. H.W. 715 and H.W. 716, are situated on the shore of Big Vermilion lake, about 35 miles northeast of Dinorwic on the Canadian Pacific Railway, and about 4 miles from Graham on the Grand Trunk Pacific Railway.

The deposit lies in a depression between a rocky ridge which strikes somewhat north of east, and the shore of Big Vermilion lake. In runs into the lake towards the west end. The surface is covered by a heavy blanket of boulder clay varying from 8 feet to 20 feet in thickness. The only place where the gossan cap was exposed was on the shore of the lake where wave action had removed the clay cover. The lake derives its name from the discolouring of the water by iron oxide from this gossan cap, and the discovery was made by a prospector when searching for gold ores.

Two shafts have been sunk on the ore body. Number 1 shaft is vertical, 8 ft. x 10 ft. in section, and is used only as a manway and for pipe lines and ventilation. It is 260 feet in depth. This shaft is equipped with a standard 41 ft. Lidgerwood single drum hoisting engine. Number 2, the working shaft, is a 3-compartment shaft sunk in the foot wall at an angle of 58 degrees. The hoisting compartments are each 4 ft. x 6 ft., and the shaft is 260 feet in depth.

The aerial tramway, which was constructed two years ago to convey the crushed ore from the rock house to the spur from the G.T.P. Ry., about 3 miles distant, has been furnished with new equipment and a new terminal erected at the spur where the ore may be either direct to railway cars or stocked in piles for subsequent loading by means of a 10-ton locomotive crane alongside.

The mine has been equipped with new rock drills of both the piston and hammer styles as well as with new mine cars, air piping, tracks, etc. Overhead stopes have been opened preparatory to the resumption of shipments during the coming season.

A new office and warehouse, dry house for the underground men, powder magazine, machine shop, water lines, mess and bunk house, as well as several cottages have been provided.

About a year and a half ago, some 6,000 tons of ore were shipped, but since then there have been no shipments. The ore mined during development work was stock-piled. It is hoped that about 25,000 tons will be sent out this season (1911), if transportation facilities will permit; this will include ore mined in development work.

The ore body has been developed for 800 feet on the 2nd level. In addition, there is considerable drifting on the 1st and 3rd levels; the total amount of drifting in December, 1911, exclusive of cross cuts, was 1,500 feet. The width of the ore body varies from 30 to 63 feet.

According to Fraleck the interbanded pyrite and rock near the hanging wall side, as disclosed by the shaft and cross-cut is suggestive of vein filling, especially as some tourmaline was observed along the northern edge of the deposit. The laminated structure of the ore, however, renders it more probable that the deposit is of the replacement type, and that the banded pyrite and rock along the northern edge represent incomplete replacement of the schist. The country rock along the hanging wall side is composed of a greenish highly calciferous schist. The gangue matter of the ore is quartz. The ore body strikes northeast and southwest, and dips to the northwest at an angle of about 61 deg.

The ore consists of pyrites (with some pyrrhotite) which apparently runs about 40 per cent. sulphur; this also being the proportion of sulphur in the lost of ore already shipped. The ore is a hard and fine grained pyrite and will be mostly lump ore, with some fines. It has proved to be an excellent ore for acid making, the residual sulphur lost in the cinder being often less than one per cent., although this will be increased by any admixture of pyrrhotite.

The mine is operated for the Northern Pyrites Company, by Robert K. Painter, of Benson Mines, New York, as consulting engineer, and H. V. Smythe, local superintendent at the mine.

**Geological Relationships.**—In discussing the geological relationship of the pyrite occurrences in Ontario, Fraleck states that pyrite deposits have been found throughout an area of approximately 170,000 square miles, including eastern, northern and Western Ontario.

On the basis of their rock associates, he divides the deposits into three classes as follows:

1. The gneissoid, comprising the Brockville and Mattagami deposits. In both cases basic dykes are in close proximity.

2. Those of the iron formation, comprising the Helen, Straw Hat lake, and probably the Goudreau lake reposits; those in the cyrstalline limestone of Eastern Ontario are similar in origin, if not in age.

3. The remainder are associated with the crystalline schists with, in almost every instance, an eruptive greenstone close by.

## PYRITES IN BRITISH COLUMBIA.

The mineral pyrites is reported from many localities in this province. For the most part these occurrences are associated with gold or copper ores, and the deposits are not valuable because of the sulphur content of the ore. At the present time no pyrites is mined in British Columbia for its sulphur, nor, so far as the writer was able to learn, is any imported. The sulphides which are mined are smelted to recover copper and the precious metals, and the sulphur is burned off. It is possible that in the future, with the development of manufacturing industries, there may be a market for sulphur content of suitable ores. Present needs are satisfied by the importation of Japanese raw sulphur, which costs between $17-$18, per ton ton, in cargo lots at seaboard points.

There are two localities, at which pyrites deposits occur that are worthy of special mention, viz.: the Hidden Creek property of the Granby Consolidated Mining and Smelting Company, and an occurrence on the Ecstall River about thirty-five miles above Port Essington, owned by the British Columbia Pyrites Company.

**Hidden Creek.**—This property is located about three-quarters of a mile from tide water, on Goose Bay at the head of Observatory Inlet. It is now controlled by the Granby Consolidated Mining and Smelting Company, which owns 14 claims and has mining rights in several others. This company has been exploring and developing this prospect as a copper property for about two years, and it is probable that a smelter will be ererted in the near future.

A large body of sulphide ore has been developed by a system of tunnels and supplementary diamond drilling. A tonnage estimated at about 6,000,000 tons of 2 per cent. (copper) ore, or about 12,000,000 tons of 1.65 per cent. ore has been shown to be present. In addition, development work has shown a very considerable tonnage of ore of a higher grade—above 5 per cent.—and a large tonnage of low grade. A large force is now employed in preparing the property for operation on a large scale as a copper mine.

Much of the ore which occurs on this property is almost pure sulphides with high sulphur content, and a large tonnage occurs that is nearly pure pyrite.

Under present conditions there is no market for the sulphur content of the ore, and, as a consequence, the sulphur will be burned off and discharged into the air in the process of smelting. Should it be warranted by market conditions at any time before the deposit is exhausted, a large tonnage of pyrites with a low copper content will be available from this mine. As the mine is practically at tide water, it would be comparatively easy to deliver the ore very cheaply at any point on the coast. After treatment in a roasting furnace to recover the sulphur content, the cinder could easily be subjected to treatment to recover the copper and other values which it would contain.

**Ecstall River.**—This property is situated on Red Gulch Creek, a tributary of the Ecstall River, at the head of tide water, and about 35 miles above Red Essington. The portal of a prospecting tunnel, which is driven into the roe, is about 2,400 feet from the river. There is said to be an iron stained band on the west side of the creek, presumably pyrites, traceable for several thousand feet, and varying in width from 12 feet to 200 feet.

The writer visited the prospect tunnel on Red Gulch Creek, but was not able to visit the outcrop on account of the weather conditions. The sill of the tunnel portal stands only a few feet above the creek and the tunnel is driven into the side of the gulch. At about 50 feet from the entry it cuts an ore body of almost pure pyrite about 15 feet in width. Ore has been stoped out on each side of the tunnel for about 20 feet and the full width of the ore chute.

Outcroppings showing pyrite are said to occur in a number of other places further up the creek, and on the side of the valley. These were not visited. Exploratory work has been confined to the opening of this tunnel.

A sample shipment of ore from the tunnel, said to be about 100 tons, is reported to have been made to the Chemical Works at Victoria. The test of the trial shipment of ore showed that it is a very satisfactory ore for acid making.

Samples which were assayed show small values in gold, silver and copper. The sulphur content varies from 40 to 48 per cent.

Further exploratory work is required to definitely determine if the pyrites ore bodies on this property are large enough to be operated economically. At present there is no market on the coast for ore of this character and no work is being done on the ore bodies.

### PYRRHOTITE IN ONTARIO.

Pyrrhotites are not usually considered to be sulphur ores, since a pure pyrrhotite contains only 39.2 per cent. sulphur, which can only be recovered with difficulty, while pure pyrite assays 53.4 per cent. sulphur. Pyrrhotites have, however, been successfully roasted in several types of fines burners, without supplying additional heat from an external source; the gas produced contains a lower percentage of sulphur dioxide than that made from pyrites. Conditions might easily arise whereby it would be economical to employ ores of this kind for acid making.

Ores of this class have been found at a few localities in Eastern Ontario, but the most important known deposits are the nickel-copper-bearing pyrrhotites of the Sudbury district. Exploration work has shown that there are probably nearly 50,000,000 tons of this ore available in the district. Much of it will contain above 25 per cent. sulphur, some of it will run above 30 per cent. Present practice is to roast the ore in open heaps, driving off slightly more than one half the sulpsur. It does not appear to be commercially practicable to save this sulphur at the present time, i.e., the cost of recovering and marketing the sulphur would be greater than the value of the sulphur recovered. The expansion of the market for sulphur diovide and the introduction of improved processes may, in the future, so modify conditions that it may be practicable to recover and market some of the sulphur which is now valueless and is thrown away under present practice.

# HEDLEY GOLD MINING CO'S. REPORT FOR 1912

The annual report of the Hedley Gold Mining Co. (operating in British Columbia) for the year 1912, includes the reports of the President (Mr. I. L. Merrill), the General Superintendent, and the Treasurer, as follows:—

### Report of the President.

"During the past year things in general, at mines and mill, have gone along very well.

"We acquired the adjoining claims known as the 'Windfall Group,' lying to the northwest of our property. Our exploration work demonstrated that the ores pass into this acquired territory, which promises well for a lang life to our mines.

"For detailed information, I submit the reports of the Superintendent and the Treasurer."

### Report of the General Superintendent.

Mr. Gomer P. Jones, General Superintendent, reported as under:—

"For the year 1912 your mill has treated 70,455 tons of ore, having an average value of $11.19 per ton, or a total value of $788,715.05. The value of the gold won was $748,133.14—an extraction of 95 per cent. The profits were as shown in the Treasurer's statement.

"Owing to the increase in tonnage, which used practically all the power available, we have been able to do but little development work on the company's properties, excepting the Nickel Plate, where stoping and development work, in the orebody, has been carried on between the No. 3 and No. 4 tunnel levels, and the ore won has proven to be of a higher grade than estimated last year. The usual reserve tonnage of 10,000 tons of broken ore has been maintained.

"Mining below the No. 4 tunnel level has been very satisfactory and has proven that the orebody, as indicated last year by diamond drill, is a valuable addition to these reserves. An incline shaft (No. 5) has been sunk in the ore for 420 feet, three levels have been opened and a fourth commenced. Drifting and sinking proves this ore to be about 16 feet in width between walls and of an average value of $14 per ton. At the collar of the incline the length of the ore shoot is 130 feet; at the 100-foot level it has been drifted on for 180 feet, and on the third level for 80 feet. These drifts are in good ore all the way, and including the bottom of the incline all the faces are in ore. This incline is in good shape to ship from, with ore-pockets in each level and plenty of good ground for stoping.

"A section of the ground under the Nickel Plate orebeds has been proven by diamond drill; also a section of the company's property lying to the north; but owing to delayed negotiations for an option on the Windfall group of mining claims, adjoining the Iron Duke (one of the company's original claims), we did not commence drilling on this ground until July. By October seven holes were put down, and three of these showed good value. The last two holes were discontinued before they entered the ore zone, owing to the severe cold weather freezing the water in the long pipe-lines. These holes would, if completed, have aided us considerably in making an estimate of the reserve tonnage; however, we have no hesitation in stating that the minimum of reserve ore, as shown by development and diamond drill, available in the Nickel Plate and Iron Duke claims, is 413,000 tons, and that this ore will average at least $11.35 per ton.

"While the above-mentioned ground was being tested, and option was held for the purchase of the Windfall group, comprising five claims, namely, the Windfall, Morning, Winchester Fraction, Big Horn, and Czar, and on October 30, the purchase of these properties was consummated. The terms of the option did not allow time to prospect the ground, as it would have been necessary to drill each hole 500 feet at least before striking the ore-bearing sedimentary beds, but from indications in the hole drilled nearest the optional property and the high value in the remaining holes, we consider these claims valuable.

"To mine the new ore-bodies, as well as the other ore-bodies below the No. 4 level in the Nickel Plate mine, we have received instructions to sink and have started another incline shaft, to be known as the Dickson incline. The intention is to sink this to 3,000 feet in depth. It is located so as to be under all the known ore-bodies, and will have payable ore above it continuously. The probability is that it will be extended next year.

"The Sunnyside No. 4 incline has been extended 160 feet, and is in promising country. Development work in the Silver Plate showed some good ore, but it is apparently cut off by a large diorite dike. Both these properties are in a good formation, with favourable conditions.

"The cost per ton for mining and milling, for the year has been reduced 53 cents, and the total cost, 73 cents, although we have been paying a higher rate of wages, and the following additions, improvements, etc., have all been charged to operating expenses: Removing the old and installing the new boiler (150 h.p.), together with the cost of the boiler, new diamond drill, new hoist, improvements to the flume, general improvements to the mill, and all mine development.

"The mill has been kept in first-class repair and is doing good work; the water-flume is also in better shape than last year; and changes have been made on the tramway, so that its operation is more satisfactory.

"Altogether we believe the last year to have been most prosperous. We expect to see the ore reserves increased during 1913.

"Development was as follows: Nickel Plate mine: sinking 420 fet, drifting 510 feet; raising, 110 feet; Silver Plate mine, drifting 140 feet; Sunnyside mine No. 4, sinking 160 feet. Total development 1,340 feet. Diamond drilling, 6,380 feet."

**Report of the Treasurer.**

The report of the Treasurer, Mr. C. D. Fraser, follows:—

"Attached is Balance Sheet as at close of December 31, 1912, and detailed statement of earnings.

"The net profits for the year were $385,880. The dividends for the year aggregated $360,000, or 30 per cent. upon the issued capital stock. The undivided profits, after payment of all dividends, were $226,841.34 at the close of the year.

"New mining claims were acquired at a cost of $145,913.13, which outlay was capitalized. All other expenses of every kind during 1912 were charged to operating expenses; these included new 150 h.p. boiler, diamond drill, hoist, etc., as shown in the report of the General Superintendent.

"The low earnings for December were caused by extra heavy development work, which compelled the crushing of an unusual proportion of low-grade ore. In addition, much trouble was caused during that month by snow." (The January, 1913, earnings were normal.)

**Balance Sheet at End of 1912.**

—Assets.—

| | | |
|---|---|---|
| Mines, mine buildings, machinery, reduction plant, etc.: | | |
| Original investment | $ 920,000 00 | |

*Including $9,834.69 interest earned on funds of the company during 1912.

# PERSONAL AND GENERAL

Mr. A. W. Allen, secretary of the Lucky Jim Zinc Mines, Ltd., proceeded from Victoria, B.C., to Kalso, Kootenay Lake, at the end of April, to attend the annual meeting of the company called for May 1 at the latter place.

Mr. Melbourne Bailey, for years actively engaged in placer-gold mining on a large scale in Cariboo, British Columbia, has arranged to return to that district for the ensuing hydraulicking season, after having spent the winter at his home in Tacoma, Washington.

Mr. T. Walter Beam, of Denver, Colorado, has bonded a number of mineral claims situated in Hedley camp, Similkameen, B.C., and has arranged to extensively prospect the ground with diamond-drills. The exploration work will be done under the immediate supervision of Mr. Gomer P. Jones, of Hedley, general superintendent for the Hedley Gold Mining Co.

Mr. E. V. Buckley, manager of the Queen gold mine, in Sheep Creek camp, Nelson Mining division, British Columbia, has informed the Nelson Daily News that sufficient miners have returned to work at the Queen mine to admit of operations being resumed at the Queen stamp mill. The men are reported to have stated that they were induced to strike by representations that have not since been found correct, so they have returned to work at the old rate of wages.

Mr. W. A. Cameron, superintendent of the Consolidated and Mining and Smelting Co's Richmond-Eureka mine, has returned to Sandon, Slocan, from a trip to the British Columbia coast, and, now that the danger from snowslides has past, has resumed work at that mine.

Mr. M. S. Davys, managing director for the Silverton Mines, Ltd., and Mr. G. Stilwell, the company's superintendent, have succeeded in overcoming the obstacles that since the destruction of the lower terminal of the aerial tramway and the Wakefield mill by fire last June had prevented a continuence of ore production. The new concentration plant, which includes provision for the Minerals Separation flotation process, is now being operated.

Mr. W. J. Elmendorf, of Victoria, B.C., manager for the Portland Canal Tunnels, Ltd., has made a progress report to the directors of the company on the work of driving a 2,200 ft. cross-cut adit the company undertook and which was commenced last September. By April 1, ultimo, the face of the tunnel was 823 ft. from the portal, and it was estimated that the 1,000 ft. mark would be passed by May 1. This exploratory work is the most important yet undertaken in Portland Canal mining division, for it will prove ground to a depth of 2,200 ft. below the level of the workings of the Portland Canal Mining Co., from which about 8,000 tons of ore has been mined.

Mr. Jay P. Graves, vice-president and general manager of the Granby Consolidated Mining, Smelting and Power Co., Ltd., has returned to his headquarters in Spokane, Washington, after having spent the winter in southern California.

Mr. S. W. Hall, of Butte, Montana, who is superintending the development of a part of the holdings in that camp of the Butte-Duluth company, which has come into some prominence lately in connection with the claim that nearly pure metallic copper is being produced by a leaching and electrolytic refining process in use by that company and the Bullwhacker, operating in the same district, was formerly managing mines at Rossland, B.C. He is a son of the late Mr. W. E. Hall, at one time manager of the Le Roi mine, Rossland, who came to his death in January, 1898, by falling down one of the shafts of the mine.

Mr. J. M. Harris, of Sandon, Slocan, B.C., well known as one of the principles in the long-drawn-out litigation between the Star and Byron White companies, involving extra-lateral rights, has lately been visiting the Panama canal.

Mr. R. A. A. Johnston, mineralogist of the Geological Survey of Canada, who has been on, a vacation spent a few days in Victoria, B.C., in the course of his holiday wanderings.

Mr. Oscar Lachmund, general manager for the British Columbia Copper Co., last month visited Princess and Voigt's camps, Copper Mountain, Similkameen, B.C. He was accompanied by Mr. Frederic Keffer, the company's engineer and geologist.

Mr. Douglas C. Livingstone (B.Sc.,McGill, 1906), associate professor of mining engineering at the University of Idaho, Moscow, Idaho, has been examining the Center Star property, Elk City, Idaho, which is under bond to Pittsburgh, Pa., capitalists.

Mr. T. J. Lloyd, underground superintendent at the Van-Roi mine, Slocan, has given the Consolidated Mining and smelting Co., a bond on a group of mineral claims situated near Four-mile Creek, Slocan lake district, B.C.

Mr. C. H. McDougall (B.S.c., McGill, 1905), superintendent of the Consolidated Mining and Smelting Co's St. Eugene and Sullivan Group mines in East Kootenay, was lately convalescent after having been ill in the Kootenay Lake hospital at Nelson.

Mr. Alfred McMillan has returned to Northport, Washington, from a stay at the Halcyon Hot Springs, Arrow Lake, B.C. He is in charge of the smelting works at Northport, and other property of the Le Roi Mining Co., in liquidation.

Mr. I. M. Merrill, president of the Hedley Gold Mining Co., recently paid a visit to that company's mine and stamp mill in Hedley camp, Similkameen, B.C.

Mr. W. H. Nichols, of New York, president of the Granby Consolidated M.S. and P.C., has gone to Europe on a two months' vacation.

Mr. Fred S. Peters, superintendent of the Le Roi mine, Rossland, B.C. has been in the hospital in that city for treatment during illness.

Mr. M. E. Purcell, superintendent of the Centre Star-War Eagle group of mines, in Rossland camp, is making arrangements for the reception there of visitors who will attend the Fifteenth General Meeting of the Western Branch of the Canadian Mining Institute, to be opened in Rossland on the evening of May 22. As the meeting will be a joint meeting with the Spokane Local Section of the American Institute of Mining Engineers, it is expected the attendance will include a number of visitors from the State of Washington and several from Idaho, as well as others from the Kootenay and boundry districts of British Columbia. The provisional programme is May 22, evening meeting; May 23, visit to local mines in daytime, and evening meeting; May 24, visit to Consolidated and M. and S. Co's smeltery and refinery, at Trail, and amusement evening.

Mr. E. C. Semmens, who has had a lengthy gold mill experience in Western Australia and West Africa, has been apointed to charge of the 10-stamp mill, on Cadwallader creek, Lillooet district, British Columbia, of the Coronation Gold Mines, Ltd. The company two years ago aquired the Ben d'Or gold mine and mill and other mining property in the vicinity, and since then has done much underground development with promising results, so with sufficient ore developed for stoping the mill is to be operated this season.

Mr. R. J. Spry, is superintendent of the Eureka mine, near Nelson, B.C., which property is being developed by the British Columbia Copper Co., under option of purchase.

Mr. Thos. R. Stokett is being heartily congratulated on the satisfactory results achieved at the New Reserve Shaft Mine, near Nanaimo, Vancouver Island, which mine is being opened under his direction (see Canadian Mining Journal for Apiil 1, p. 212). Coal has been entered at a depth of 1046 ft., and the seam is reported to be 10 ft. in width of coal of excellent quality.

Mr W. J. Sutton, of Victoria, B.C., has been nominated as chairman of the Western Branch of the Canadian Mining Institute for the ensuing year, to May, 1914. It would be particularly appropriate for the branch to have its chairman at the time of the visit to British Columbia of excursion parties of the International Geological Congress, a geologist so well known in the province as is Mr. Sutton, so his election by acclamation may be expected.

Mr. E. E. Ward, of Ainsworth, B.C., superintendent of the Silver Hoard mine, had an unpleasant experience recently. He was going up from Kootenay lake in one of the buckets on the No. 1 mine aerial tramway when something went wrong and the cable stopped running. Hung up during a snowstrom, he was in a predicament until a miner climbed one of the towers and threw him a rope, by means of which he lowered himself to the ground.

Mr. W. P. White, of Spokane, who, some years ago, was superintendent of the St. Eugene lead mine in East Kootenay, during its period of greatest production, was lately in Boundary district of British Columbia.

Mr. W. R. Wilson, of Fernie, B.C., general manager for the Crow's Nest Pass Coal Co., was in Toronto last month attending the annual general meeting of the company.

Prof. Chas. E. Van Barneveld, recently appointed chief of the Mining Department of the Panama-Pacific Exposition, is Professor of Mining Engineering at the University of Minnesota, Minneapolis, Minn. He is a McGill University graduate (B.A.Sc.,1895). The Engineering and Mining Journal says: Professor Van Barneveld is the Dean of the School of Mines of the University of Minnesota. He is preparing to take up the exposition work immediately. He held a position in the University of Minnesota for fourteen years, and during that period travelled extensively in behalf of the University. For six years prior to that period he was engaged in practical mining, in the south-western States and in Mexico. He is the author of "Iron Mining in Minnesota." He was formerly a resident of California and is a land-owner in the Sacramento and San Joaquin valley. The mining building to be erected at the exposition will occupy an area of 350,000 square feet. It is proposed to make the exhibit greater than that of any previous exposition.

# PLATINUM IN BRITISH COLUMBIA

The following is an excerpt from the chapter on "Platinum and Allied Metals," by Mr. Waldemar Lindgren, in the United States Geological Survey's valuable report, entitled "Mineral Resources of the United States, 1911." (Part I. pp. 1000-1001.)

"British Columbia.—The presence of platinum metals in British Columbia has been known since 1887. The upper branches of Similkameen river are known to contain platinum, especially the North Fork, usually referred to as the Tulameen river. A considerable black production was at one time maintained from these gold and platinum-bearing deposits. (See Camsell, Chas.; Platinum Mining in the Tulameen District; Jonrual Canadian Mining Institute, Vol. XIII., 1910.) Camsell estimates the total production of crude platinum from this district at 9880 ounces. The richest platinum ground was found on Tulameen river between the mouths of Slate and Champion creeks. On Tulameen river no platinum was found above the mouth of Champion creek, and below Slate creek the grains became finer and the quantity gradually decreased. The platinum in some cases was present in a ratio of 1 to 3 by weight, as compared to gold. During 1911, active prospecting has been carried on, and it is stated that workable ground has been discovered. Dredging is the process which it is intended to apply to the deposit. During the last few years the annual production of platinum from some of these placers has amounted to only a few ounces. Statements in the press are to the effect that the depth of bedrock averages 12 feet. A company organized in Vancouver has leased some 20 miles of Similkameen and Tulameen rivers from the Government. The production for 1911 is estimated at 30 ounces. Much of the gold and platinum in this district is coarse and the nuggets have not travelled far from the original source. Much of the gold is still embedded in quartz, while the platinum is often associated with chromite, olivine and pyroxene. Kemp mentions platinum intergrown with olivine and octahedral chromite from the district. One of these specimens shows the contemporaneous development of the three minerals very clearly. The rock from which the platinum was derived is probably a belt of basic intrusives, mainly peridotite, having a flanking border of pyroxenit. Kemp concluded that the original sources of the platinum was in both the peridotite and the pyroxenite, and this conclusion is corroborated by Camsell. The heavy minerals associated with platinum, beside those mentioned, are magnetite and native copper. An analysis of the crude platinum gave, according to G. C. Hoffman, quoted by Camsell, the following results:—

| | |
|---|---|
| Platinum | 72.07 |
| Palladium | 0.19 |
| Rhodium | 2.57 |
| Iridium | 1.14 |
| Osmium | .... |
| Copper | 3.39 |
| Iron | 8.59 |
| Osmiridium | 10.51 |
| Gangue | 1.69 |
| | 100.15 |

"Kemp assayed a number of specimens of platinum-bearing rocks, such as serpentine, chromite, pyroxenite, and peridotite, from this district and found in most of them traces of platinum. Some of the selected chromite gave half on ounce of platinum per ton. Other samples contained from 0.1 to 0.3 per cent.. of the metal. It is exceedingly improbable, however, that valuable deposits of platinum will be found in the parent rock.

"Reports were current during 1911 of a discovery of platinum metals at and near the Granite-Poorman mining property, a few miles from Nelson. A well-defined dike bearing these metals is said to have been traced for several miles in the general direction of Forty-Nine-mile creek and Kootenay river. A statement is made by E. Jacobs in the Canadian Mining Journal of September 1, 1911, that the rock containing the platinum metals is serpentine and probably an altered peridotite. The predominent metal is said to be palladium, though platinum and other allied metals are also said to occur. Whether the find is of economic importance is not certain. The existence of a new metal named canadium has been reported in this serpentine rock, but the discovery has not been confirmed."

In his observations in the "Determination of the Platinum Metals," Mr. Lindgren includes the following:—

"The correct determination of platinum metals is somewhat difficult, and mistakes are often made by inexperienced chemists and assayers. It is difficult to say how much of the mistakes found in reports of new discoveries of platinum in the current press is due to such inexperience and how much to deliberate fraud. The most ridiculous statements are often made. A statement was made, for instance, in 1911, of a discovery of an 'immense bed of Osmium near Boise, Idaho.' The analysis was given as follows:—

| | |
|---|---|
| | Oz. per ton. |
| Gold | 2.3 |
| Iridium | 0.1 |
| Osmium | 20.0 |
| | Per cent. |
| Tungsten oxide | 5.0 |
| Tin | 0.25 |
| Cobalt | 0.5 |
| Nickel | 1.0 |

"Other statements were current of a discovery near Merlin, Oregon, of a rock containing tin and platinum. It was claimed to contain from 1 to 65 ounces of platinum per ton, and said to occur 'in a mineralized zone 600 feet wide, with 15 feet of spherulitic gangue and 8 feet of pitch-blende.' It is unfortunate that such statements should find even temporary credence."

(Note.—The statement attributed b yMr. Lindgren to Mr. E. Jacobs was contained in a quotation made by the latter, as follows: "E. R. Widdowson informed the Nelson Daily News that 'palladium is the predominating metal of the platinum group discovered near Nelson by Mr. A. Gordon French. It is obtained from a serpentine dike, which is probably an alteration of a peridotite dike. The dike material varies in colour from a dark green to a dark yellow, and is so soft that it can be mined with a pick. The metal is a hard, silvery white substance, but is not visible in any of the ore I have assayed. In all I have made some 50 or 60 determinations for palladium, and the other rare metals, for my various clients, and I am well able to confirm the presence of the metals discovered by Mr. French.' ")

# THE TRANSMISSION OF POWER BY COTTON ROPES

*By E. EDWARD HART, M.A.*

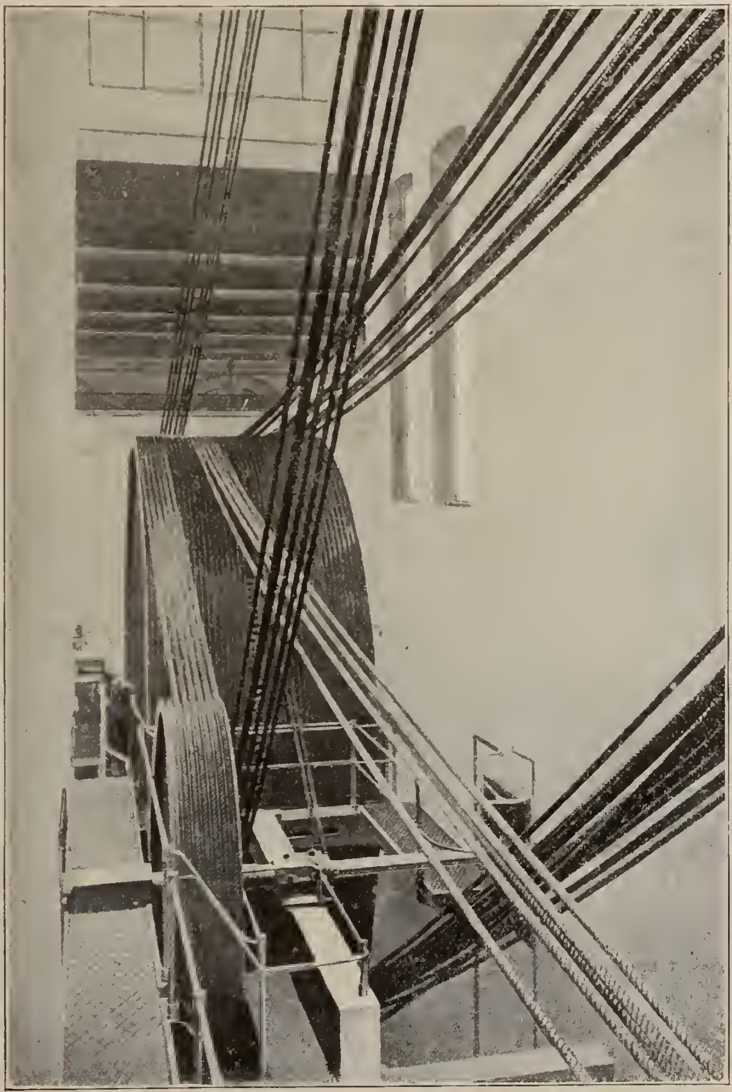
A Paper Read Before the Association of Engineers-in-Charge

The method of transmitting power from one pulley to another by means of ropes is generally termed rope driving. The rims of the pulleys are specially grooved to receive the ropes, and the power is transmitted by means of the frictional resistance between the rope and the pulley groove.

There are two systems in use: (1) The American or continuous system, where one long rope is wound continuously around both driving and driven pulleys, the last wrap being carried across the width of the pulleys back to the first groove by a carrier pulley set at the required angle. This is extensively used in America, but rarely found elsewhere; (2) the English or separate rope system, where each rope on the driving pulley runs straight and true into its corresponding opposite groove on the driven pulley. This is by far the commonest practice, and is the one to which I shall confine my attention.

For main drives, both three and four-strand ropes are used, and usually vary from 1-in. to 2-in. in diameter; but on small fans and fast-running textile machinery, smaller bands and ropes, between $\frac{1}{4}$-in. and 1-in. diameter, are more suitable. The rope-speeds most frequently employed are from 2,000 to 5,000 feet per minute.

The earliest ropes used for power transmission were probably of leather or hemp, and though there are one or two instances of main drives on record in the early years of the nineteenth century, it was not until about 1860 that Messrs. James Combe & Co., of Belfast, introduced rope driving for large powers. From Ireland the system spread to Scotland, and in a short time it was well known and used by the manufacturers of Lancashire and Yorkshire. Leather ropes were soon discarded owing to their expense and the difficulty of their manufacture and hemp ropes took their place. This was probably due to the fact that hemp was easily

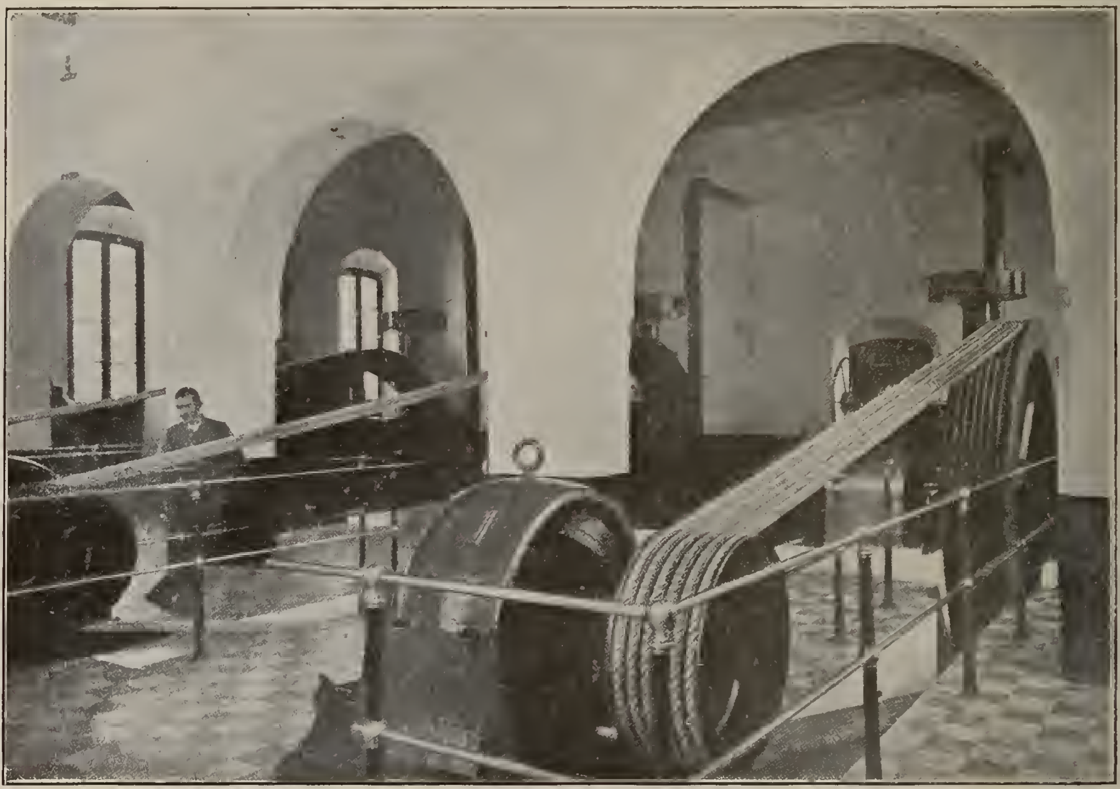


**Rope-race in a Modern Mill.**

obtainable in Belfast and Dundee, being largely cultivated in those districts.

Although several hemp driven ropes are running today, owing to the harsh nature of their fibre it was soon discovered that for power transmission, ropes made from cotton gave far better results. It is probable that from the very first cotton bandings or small plain laid ropes were used for driving the cotton-spinning frames in the Lancashire mills. Certain it is that my grandfather, who died in 1861, had been making them for many years. But the idea of driving a whole mill with ropes by having the engine flywheel grooved for their reception does not seem to have been adopted in Lancashire and Yorkshire until about five or ten years after this date. Even then ropes like the ones used in Belfast and Dundee were used at first, as they were purchased, probably, along with the engine. In the heart of the cotton-spinning district the change from hemp

The stopping of a mill owing to broken gearings is now practically unknown, and it is only necessary for one to have had the experience of working in close proximity to a large geared engine to appreciate the absolute noiselessness of a well-designed rope drive, and its freedom from vibration. As regards first cost and maintenance, a rope installation is very much cheaper than leather belts, or shafting and gearing, and where space is a consideration, it is often possible to put up a successful rope drive where there is literally no room for any other system. Electrical engineers have found it very useful in adjusting velocity ratios of shaftings, as, by using rope drives they are enabled to use higher speed, and consequently lower-priced motors. Besides this, ropes will transmit a large temporary overload without slipping, and it is possible to greatly reduce capital charges by driving a series of machines, or lines of shafting, from one motor.



**Three Sets of "Lambeth" Ropes Driving Dynamos from Gas Engines at a Mine in Spain.**

to cotton was not long in coming. And when once cotton ropes had been properly tried, their marked superiority was at once so apparent that they almost immediately displaced hemp ropes for power transmission. And to-day, with one or two notable exceptions, cotton ropes have entirely superseded hemp ropes for transmitting power in every part of the world where rope drives are to be found. And though they were only used at first in textile factories, the superior pliability of the cotton fibre has led to its adoption in mills and works of every description.

As years went on, the advantages of the system were more and more recognized. In connection with steam engines, gas engines, oil engines, and water and steam turbines, it was found that large mills several storeys in height could be easily driven from one prime mover, and that power might be transmitted to shafts over 100 feet away, without the use of long lines of heavy and expensive shafting or gearing.

The resilience of ropes, too, is found to considerably reduce the wear and tear of machinery, and they are being more and more used in steel rolling mills, cement works, and rubber factories, where sudden and severe overloads are constantly being met with. Another advantage is that, with the English or separate rope system, should a rope show signs of wear, it can be removed during the dinner hour without causing a stoppage of the mill, and can be respliced at any convenient opportunity, say the end of the week, without any excessive strain being put on the rest of the ropes. Rope gearing is also more positive in its transmission than belting, and consequently no allowance need be made for slip.

### The Loss of Power in Rope Transmission.

Several experiments have been made from time to time to ascertain the loss of power in driving with belts and ropes, and to compare their efficiencies.

(To be continued.)

# SPECIAL CORRESPONDENCE

## ONTARIO

### PORCUPINE, SWASTIKA AND KIRKLAND LAKE.

Owing to the giving away of the flume at the Sandy Falls plant of the Northern Ontario Light & Power Company, as a consequence of the tremendous floods north of the height of land, the power situation in the camp is more serious. There is for the time being no electrical power in the camp. Most of the companies, however, have their own steam plants, and they will revert to them until the break has been repaired. The operations have outgrown these plants in many instances and production or development will have to be curtailed, but in only rare instances has the failure of electrical power caused a complete shut down. The Hollinger has reverted to their steam plant, which, fortunately, has been considerably augmented since Sandy Falls enabled them to run with the electric current. Progress is being made with the repairs at the Waiwaiten Falls, and the plants obtaining power from this source should soon be able to hook up again.

The floods which have distressed the whole of the country sloping towards Hudson's Bay are phenomenal, and there is no cause to look for a repetition of these disasters.

An organization, unimportant in its inception, but of significance, is the Northern Prospectors' Association, which has been formed at Porcupine. This is purely local at present, but may spread all over the field. It is formed for the ostensible purpose of promoting the interests of prospectors, particularly in relation to legislation. It is an organization which certainly has no forerunner in Ontario.

In the first month's run at the McEaeney mine the mill heads ran $30 to the ton. The mill at this time was treating on an average of fifty tons per day.

The outstanding feature of the Kirkland Lake camp is the fact that one company has shipped $32,737.44 in gold from an open cut and a shaft 115 feet deep. As there was but 73.85 tons of it, it works out at approximately $448 to the ton. This is a conservative estimate, as the gold is reckoned at $20 to the ton only. It is also remarkable that the silver contents pay for freight and treatment and leave only haulage to Swastika station and mining to be deducted. The figures are so remarkable that they are given in full:

| Tons. | Gold ozs. per ton. | Gold contents. | Value at $20 per-oz. |
|---|---|---|---|
| 1.85 | $18.60 | $34.41 | $688.20 |
| 19.90 | 22.50 | 447.75 | 8,855.00 |
| 21.60 | 19.75 | 422.72 | 8,454.24 |
| 30.50 | 24.00 | 732.00 | 14,640.00 |
| 73.85 | | 1,636.87 | $32,737.44 |

**Silver Contents.**

| Tons. | Silver. per ton. | Silver per oz. | Silver at 60c. an oz. |
|---|---|---|---|
| 1.85 | 22.70 | 41.99 | $24.19 |
| 19.90 | 23.40 | 465.66 | 279.39 |
| 21.60 | 33.56 | 724.89 | 434.93 |
| 30.50 | 35.00 | 1,067.60 | 640.20 |
| 73.85 | | 2,300.04 | $1,378.78 |

The first shipment of 1.85 tons was a sample lot from the outcrop of five veins including No. 2, or the main vein, which furnished all the remainder of the shipments to date. All of the above ore with the exception of the last shipment came from an open cut on the No. 2 vein. This open cut had an average width of 32 feet and it was put down 24 feet before the incline shaft was commenced. The last shipment was made from the incline shaft, put down to a depth of 115 feet on the vein. The shaft has made 125 dollars per foot net profit. The main high grade vein which alone has been shipped will average from ten to twelve inches in width. The management claims that the milling ore on the foot wall and hanging wall has a total width of twenty feet and will run $20 per ton.

The No. 2 vein from which all the ore has been taken has been stripped for 390 feet till it dips under a heavy overburden at the east end.

The high grade streak is not more than two or three inches wide on the surface and was so little impressive that most of the consulting engineers of the big companies turned it down even at the small price that was asked for it a year ago. Where the vein has been mined is entirely in coarse conglomerate, but it appears to fuse with the gray porphyry at the east end. The first ore was mined on Nov. 18th. There are several other promising veins on the property, No. 3 has been stripped for 700 feet and promises to make a good body of milling ore. It is entirely in the porphyry.

The first unit of the mill should be running by the middle of the month, and there are 2,000 tons of milling ore out of development already broken. This little plant will handle at least fifteen tons per day.

Since the first of December 900 claims have been staked and filed near Swastika. Apart from the Foster no real mining has been attempted. Two shafts have been put down to the fifty-foot level, but that is all. The camp is quite in the making, but it may be said that so far as development has proceeded it has yielded quite satisfactory results. Another point in the favour of capital here is that the prospector is sweet reasonableness itself in comparison with his attitude either in Porcupine or Cobalt, Gowganda or Elk Lake. The Foster was secured on a working option for a few thousand dollars, and though prices have necessarily advanced since then they are comparatively modest. The Hughes Teck has a shaft down to the fifty-foot level and it is said that it has stood up well under careful sampling. Harry Oakes, one of the pioneers of the camp, also has some promising claims and good finds have been made on the Orr, now the Wettlaufer properties, the Hunton and some others.

The six miles long wagon road from Swastika to Gull Lake which promises to be the centre of operations is not in good shape just now, but can easily be made reasonable with the expenditure of a little money. The Government with commendable promtitude has made a grant of $10,000 for the road and Mr. Whitson already is making his plans.

At Swastika, the Lucky Cross mill is now running and is said to be making a satisfactory recovery. The cutting of the No. 16 vein at the 200-foot level has greatly improved the prospects of this mine. At one spot where a blind vein makes junction there is ten feet of milling ore and the vein has a normal width of three feet of ore that is decidedly of better grade than at the upper level.

Stamps are also dropping at the Swastika mill, and the first clean up of approximately $3,000 has been made as the result of 26 days' run.

Most of the members of the Lucky Scott party that adventured to Labrador last year are going to the east coast of Hudson's Bay.

Sam Itisse, of the Otisse mine, Elk Lake, is heading the first party towards placer fields. They have gone to Cochrane, whence they will strike with six months' provisions up to the Bell to Ruperts House and then probably to the East Main. Two other parties will also be equipped this year for much the same journey, one from Ottawa and one from Toronto.

The Gold Fields, Limited, at Larder Lake, is very materially raising the capacity of its plant by adding four tube mills and a cyanide plant. The mill is now treating about 75 tons per day of low grade ore. The d'Or Huronian mine, about eight miles from them are putting in a plant to work an ore body with a promising outcrop. The Dane Mining Company, about eight miles from Dane Station, is also busy again so that the whole section is quite active.

**COBALT, GOWGANDA AND SOUTH LORRAIN.**

Permission to drain Kerr Lake and keep it drained for seven years was given in Toronto to the Kerr Lake and Crown Reserve Mining Companies by Mining Commissioner T. E. Godson. The terms of the order are to be fixed after the notice to the other mines has been served. This is the first application of its kind made to the Mining Commissioner under his increased powers granted under the Mining Act. At the hearing the Penn Canadian mines, the Bailey-Cobalt and the Kerr Lake Maestic Mining Company were the only companies represented from among those continguous to the lake. It is expected that the work of pumping out and draining Kerr Lake will be commenced about July 15th by the two mining companies.

If the Cobalt Lake Mining Company obtains consent to pump out Cobalt Lake the company promises through its Cobalt manager to spend thousands of dollars to make the bottom of the lake an amusement park. Permission will be asked of the Mining Commissioner to allow the lake to be drained at his next sitting, probably the first week in June. If the permission is granted work will be started immediately. Two large centrifugal pumps, each with a capacity of 3,000 gallons per minute, will be placed on scows and commence operations. It is the intention to pump into the old outlet which runs round by the Right of Way and La Rose mines, and it is expected that in five months the entire 5,000,000 gallons of water now contained in the lake will be pumped into Lake Temiskaming. The cost of pumping the water from the lake will be in the vicinity of $50,000, while it will release several million ounces.

While the Hudson Bay Mining Company is seeking to consolidate its holdings in the north by developing new fields, it is not neglecting the central property. On two levels ore is being broken from stopes thirty feet wide. The average width of the stopes is from twelve to fourteen feet. There is no definite area of enrichment. Sampling alone determines how wide the rock can be mined at a profit. Stoping this width an average mill head of 22 ounces can be obtained, exclusive of the high grade which is still hand-picked. This ore is being mined for $2.25 per ton, and the twenty-stamp mill is treating on an average of 70 tons per day. The duty per ton last month was 3.67 tons per stamp.

After lying idle for more than eleven months, the first round of holes fired in the north face of the main drift at the 150-foot level of the Bellellen mine, of South Lorrain, showed high grade ore. This was four to six inches wide. Where the drills were started the vein, while it showed native silver, was not classed as high grade. But with the first round of shots last week real bonanza ore as it is reckoned in Cobalt was shown.

The fear of a strike which has been in the air for the past two or three months has been cleared by the decision of the union not even to take a vote on the matter. There was an attempt of the Socialists who have infested the Porcupine camp to force a declaration on the operation of the eight-hour bill, but the good sense of the majority of the members voted them down. The strike leaders from Porcupine descended on the Cobalt camp some weeks before the matter came to a head and succeeded in capturing the organization. They imported some agitators and endeavoured to foment a strike. But the majority of of the miners even in the union were not in favour of industrial disturbance. This is the second time this year that the Cobalt union has declared against a strike in the silver camp.

## BRITISH COLUMBIA

There is little change in the labour situation at British Columbia mines, except that an attempt was being made at the close of April to induce the miners employed by the Western Fuel Co. at its several coal mines in the vicinity of Nanaimo, and those of the Pacific Coast Mines, Ltd., at South Wellington, all on Vancouver Island, to strike. On May 1 the Victoria Times published the following:

"A manifesto has been issued by Robert Foster, president of the United Mine Workers of America, District 28, declaring the commencement to-day of a strike at all the coal mines on Vancouver Island, and requesting all miners to cease work until the companies for which they work concede them an advance in wages.

"This manifesto is the result of orders issued by the Seattle (Washington) representative of the International Union of United Mine Workers, Frank Farrington, who, in issuing instructions for the strike manifesto to Mr. Foster, declared that this was the result of the lack of interest taken by mine-owners on Vancouver island in the invitation to atttend a conference on the subject some months ago.

"The instructions issued call for a strike of all men employed in and around the mines at Nanaimo, South Wellington, and Jingle Pot, the strike to continue until a joint working agreement between the United Mine Workers of District 28 and the mine-owners on the island shall have been secured. The men ask for increased prices for labour and improved conditions of employment.

**No Unlawful Tactics.**—The manifesto, while calling the men out of the mines, asks that every effort be made to prevent unlawful or abusive tactics by the men. The names of all who refuse to respond to the strike call will be blacklisted and published throughout Canada, Great Britain and the United States. A force of men sufficient to protect mining property will be permitted to work so long as the companies shall not attemut to ship coal, but all men not engaged in this way are urged by the manifesto to join the strike, the International Union having promised all the men involved, whether union or non-union, financial support so long as the strike shall last.

"Should all the men at the mines affected by the manifesto go out it will mean that something like 2,000 men will be involved in the strike, although the local agents have not up to the present been apprised of any definite action with respect to the affair."

**Miners Resent Order.**—A despatch from Nanaimo, published in this evening's "Times" (May 2), is as follows: "Mr. Foster's action in calling a general strike was taken without first submitting the question to a vote of the miners concerned. Of the 1,500 employed in the Nanaimo mines, only 200 are members of the organization which has called the strike in the local mines and a large majority of the men resent the action taken by this small minority. A mass meeting of all employees will be held to-night, when a secret ballot will be taken on the question as to whether Nanaimo miners will recognize a strike order of the United Mine Workers. It is said that there will be an overwhelming majority in favor of continuing work, as the men are working under an agreement with the Western Fuel Company, which has still at least five months to run and which they feel in duty bound as honourable men to respect."

It may be added that some time ago the Nanaimo miners refused to go out on strike in sympathy with those at the Cumberland and Extension mines of the Canadian Collieries (Dunsmuir) Limited, and at which non-union labour has since been employed, with an increasingly large number of men working at Cumberland and a commencement made with some 200 men at Extension. Published figures show that during three months ended March 31 the output of coal from the Cumberland mines was 96,818 tons, as follows:—January, 29,541 tons; February, 30,036 tons; March, 37,241 tons. For the week up to April the latest figures at hand, the output was 9,191 tons, or better than 1,500 tons a day.

# PRINCIPLES OF MINE VALUATION*

By JAMES R. FINLAY

I have always supposed, and I think that nearly all mining engineers agree with me, that there are three or four fundamental factors about a mining prope which determine its value. These are:

1. The average cost of securing the products of that mine.

2. The average price at which those products can be sold.

3. The rate of production of the mine.

4. The time for which that output can be maintained.

I do not intend to go into detail as to any of these factors, but to point out some things which I think are worth considering, in the hope that later you will think about them and learn the details for yourselves.

In regard to the average cost: In the case of going concerns, that average cost can be obtained empirically by simple reference to the books—to what has actually been done on the property. That seems and sounds exceedingly simple. As a matter of fact it is not easy. I made the mistake once of thinking that it was. I bought a mine in Joplin, Mo., to be specific, on a record of its cost for six months. The reason I did not go further back was that older records were not to be had, and also because during this particular six months the property had reached a substantial basis. I figured that the concentrates from that mine could be produced perty should produce so much ore and that the price would be a certain figure. It happened that developments proved that I was right about the price and the quantity of ore on the property, but they also proved that I was wrong on the question of costs. It cost us nearly 75 per cent. more to produce concentrates from that ore than the record of the property showed. There were times when we produced concentrates for $15 a ton, but that was not representative of the while period of working the mine. I think you will find today that a great many of the cost statements given out by different companies for fixing the value of their stocks are only temporary or occasional costs, and will not stand analysis, and cannot be maintained during the whole life of the property.

Then there is another factor in which people deceive themselves, unconsciously, but in the simplest and most obvious ways imaginable. They keep on doing it, always have done it, and I suppose always will do it. That is, by failing to see the relation between expenditures that are for plant and those for keeping it going. In keeping books it is very easy to say that the construction of a building, the remodeling of a mine, or the building of a new mill, is something that will not happen again, that it belongs to the property and not to the operation; to a certain extent that is true, but it is a fact, which I have verified by looking up a great number of mines, that the so-called operating costs are ordinarily not more than 60 to 80 per cent. of the total cost. Until a mine is shut down, there is always some expenditure to be undertaken which a bookkeeper may think will not be repeated, that it belongs to the plant, but these things keep occurring so constantly that one who is figuring on costs must count on them. That is, to form an estimate that is correct or approximately correct will require a good deal of judgment and experience.

Another thing I believe to be true is that any estimate of cost, or valuation, or anything relating to the future, is a good deal of a guess. One who thinks he can estimate a cost, whether of a going concern or a concern to be started, to a fraction of a cent, or to any fixed amount is simply mistaken. All you can do is to put a round figure which seems to be pretty near the facts. Of course, the difficulty of estimating costs at a mine which is not yet opened is considerably greater than at a mine that is going, for very obvious reasons.

The next fundamental factor in forming an idea of the value of a mine is the average price of its product. I will go so far as to say that this is the most important factor to be considered. The literature on this subject, I think, has not done justice to the importance of prices because apparently a good deal of the best thought given to the subpect of valuations has been by English engineers who had in mind principally gold mines. Gold, of course, is the only product of mines the value of which is fixed; consequently most of the discussions on mine valuation among engineers have been devoted to the third factor, which I will come to later, viz., the uncertainties in amount of ore in a mine and the part that deveolped ore plays in the estimate of a total valuation.

*An address delivered at The Columbia School of Mines.

As an example of the tremendous importance of the price of a product in mine valuation, I will cite from my report on the Michigan mines. At the time of that report, the price of copper was 12¼c. per pound. A group of copper mines in Michigan were producing, and had been producing 200,000,000 lb. of copper per year at a cost of 10c. per pound, in round figures. I valued the mines on the assumption that the average price of copper would be 14c. per pound as against the current price of 12¼c., and I put a valuation of about $70,000,000 on that basis. Roughly, at 14c. a pound, the earnings would be $8,000,000 a year, and the total value of the group would be nine times that, or $70,000,000. You will find it is a difficult thing in commercial transactions to figure steadfastly on a price that is different from the present price. When I talked about copper averaging 14c. a pound, many said, "That is not the present price, it is 12¼c." Some thought the price might go even lower instead of higher. I think if I had not been prepared by several years' study of that very subject, I would certainly have used a lower figure than 14c. a pound for the average price of copper. At any rate, the value I put on them was nine times their annual income at 14c. If I had used the current price of 12¼c., their annual income would have been only $4,500,000. As a matter of fact, within less than 12 months after the report was made the price of copper had gone up to 17¾c., and the usual proportion of people thought that the price would go still higher, and that this might be the average. If it had been the average, the earnings of these mines would have been nearly $15,500,000 at that price of copper.

Now let us look at what these figures mean in terms of the life of a mine. If I had figured that the mines were worth $70,000,000 at a price of 12¼c. per pound, I would have had to believe that the mines, on the average, were good for 40 years' life, instead of about 13 years. If, on the other hand, I had assumed that the price would be 17¾c., in order to make the mines worth the price I put on them they would have to last only five or six years. Therefore the fluctuations of price in less than a year corresponded to an extension in the life of those mines from five or six years to 35 or 40 years. Here again I am dealing in a mere approximation. I suppose these mines produce about 20 lb. of copper per ton; therefore to get 200,000,000 lb. of copper per year you would have to mine 10,000,000 tons. Therefore, the figures that I actually used meant that I believed there was 130,000,000 tons of copper ore which could be depended on. That is an enormous amount of ore. Figured roughly, that would mean a lode of solid ore five miles long, of the average width of 12 ft., and 5,000 ft. deep; it was actually obtained by projecting the production of the mines and the development of the mines far below their present position. Now if I had to estimate on 12¼c. copper, I would have had to figure on 40 years' life, or I would have had to believe that there were 270,000,000 more tons there than I thought I was justified in believing. On the other hand, if we put the value at 17¾c., I should have had to figure on only 50,000,000 or 60,000,000 tons of ore. Therefore, I say, as affecting the values of mines, the actual fluctuations of price within one year were equal to an uncertainty in the ore production in those mines of more than 300,000,000 tons. An engineer is not likely to make a mistake like that with mines so fully developed as these Michigan properties, many of which are worked to a great depth, are well managed, and have their outlines very well shown. He could, however, easily make just as important a mistake as that in figuring on his average price of copper.

As a matter of fact, I do not think the 14c. price I used was an accurate figure. I have believed that copper would average more than 15c. per pound, taking into view the development of the business, but 14c. was as far as I thought I could go. I do know that mines have been valued within the last five years on prices estimated all the way from 12c. to 20c. Just imagine what a difference that makes in the estimated value of those mines! I know a very important mine in Mexico, the organizers of which believed that copper would not average less than 20c. per pound. I know of mines, on the other hand, that are being valued on an expectation of 12½c. per pound. The same uncertainty applies to all kinds of metals.

I ran against the same difficulty with another group of mines during that same Michigan study. In the iron mines I assumed a price for iron which happened to be almost the same as the price for the year 1911, which was a dull year in the iron business. In this case, however, the price, instead of going up, as the price of copper did, went down about 50c. a ton the next year. Now the margin of profit for those iron mines, during the period that I figured on, was just about $1 a ton, so that if you take off 50c. a ton you cut the profits in two. Of course, during all this last year, I have been exposed to a good deal of criticism by the iron miners, because they say I assumed a wrong price. While it may have been wrong for the year 1912, I notice that prices for the year 1913 have been fixed lately and at a figure very close to my average, in fact, almost identical with it if certain reductions in freight rates be considered.

In both the iron and copper calculations, I have been asked a great many questions as to how I arrived at the prices I assumed. Here there are certain evidences which can be used as guides, and are well worth studying. One general fact about the prices of all mining products is that they vary in cycles or in waves, irregularly of course. If, after a period of high prices, you find that prices are definitely going down and reach a new level, it is pretty safe to believe that the lower level of prices will continue several years. On the other hand, after a period of low prices, when once the metal rises markedly, it is pretty safe to assume that it will stay at a higher level for several years. Those fluctuations are things very well worth studying. It is a matter on which you cannot form opinions right away. You will find in a year from now that you will be justified in holding a different idea from the one you may have at present.

The valuation of a mine, while in the long run it depends on the average, is influenced a good deal by the present price. If you have a copper mine that is going to last ten years, and you expect 18-c. copper for three years out of those ten, it is a matter of considerable consequence to your property whether that 18-c. price comes during the first three years or during the last three years of the life of your mine. If it comes in the first three years you will get your profits and may invest them, perhaps in other directions, and the interest on that money for the following years will be worth a great deal to you. I must confess, in regard to the question of profits, that I was wrong when I wrote my book on the "Cost of Mining" in laying too much stress on average price. I now believe the public is right when it puts a higher value on properties during periods of high prices for metals. That is merely an assertion which I offer you to think about.

(To be continued.)

## STATISTICS AND RETURNS

### BRITISH COLUMBIA ORE SHIPMENTS.

For Week Ending May 3rd.

**Rossland.**

| | Week. | Year. |
|---|---|---|
| Le Roi No. 2, milled | 350 | 6,300 |
| Centre Star | 3,064 | 50,880 |
| Le Roi | 1,050 | 21,559 |
| Le Roi No. 2 | 608 | 7,798 |
| Other mines | ... | 102 |
| Total | 5,072 | 86,639 |

### COBALT ORE SHIPMENTS.

Cobalt, May 10.—The feature of the week is the discovery at the Cochrane, which will indirectly mean a considerable amount of prospecting activity in southeast Coleman again.

The shipments for the week in pounds are:—

| Mine. | High. | Low. | Pounds. |
|---|---|---|---|
| Coniagas | 3 | .. | 201,615 |
| Trethewey | 1 | .. | 49,550 |
| Nipissing | .. | 1 | 52,691 |
| Dom. Red | 1 | .. | 87,311 |
| Hudson Bay | 1 | .. | 63,225 |
| Cobalt Townsite | 2 | .. | 104,540 |
| McKinley-Darragh | 1 | .. | 60,210 |
| Kerr Lake | 1 | .. | 60,210 |
| | 10 | 1 | 683,501 |

The shipments from the Cobalt mines to date are:

| Mine. | High. | Low. | Tons. |
|---|---|---|---|
| Coniagas | 21 | .. | 682.20 |
| Trethewey | 5 | 5 | 277.77 |
| Nipissing | 2 | 21 | 764.63 |
| Dom. Red | 7 | .. | 225.81 |
| Hudson Bay | 7 | .. | 231.83 |
| Cobalt Townsite | 22 | .. | 795.06 |
| MKinley-Darragh | 24 | .. | 822.94 |
| Kerr Lake | 8 | .. | 295.14 |
| Beaver | 5 | .. | 135.98 |
| La Rose | 24 | .. | 1,005.24 |
| Peterson Lake (Seneca-Sup.) | 3 | 3 | 220.40 |
| Temiskaming | 8 | 1 | 278.61 |
| Crown Reserve | 5 | .. | 249.95 |
| Chambers-Ferland | 1 | 4 | 159.20 |
| Colonial | 1 | .. | 21.56 |
| Cobalt Lake | 8 | .. | 140.52 |
| Penn. Canadian | 1 | .. | 32.06 |
| Drummond | 8 | .. | 219.59 |
| General Mines | | .. | 8.80 |
| O'Brien | 4 | .. | 156.75 |
| Silver Queen | .. | .. | 60.34 |
| Bailey | 3 | 1 | 182.15 |
| Casey Cobalt | 3 | .. | 109.72 |

## TORONTO MARKETS.

May 12th—(Quotations from Canada Metal Co., Toronto).

Spelter, 6¼ cents per pound.
Lead, 5¼ cents per pound.
Tim, 52 cents per pound.
Antimony, 10 cents per pound.
Copper, casting, 16 cents per pound.
Electrolytic, 16 cents per pound.
Ingot brass, 11 to 15 cents per pound.

May 12th—Pig Iron (Quotations from Drummond, McCall & Co., Toronto).

Summerlee No. 1, $26.00 (f.o.b. Toronto).
Summerlee No. 2, $25.00 (f.o.b. Toronto).
Midland No. 1, $20.50 to $21.00 (f.o.b. Toronto).
Midland No. 2, $20.50 to $21.00 (f.o.b. Toronto).

## GENERAL MARKETS.

Coal, anthracite, $5.50 to $6.75 per ton.
Coal, bituminous, $3.50 to $4.50 per 1¼-inch lump.

### Coke.

May 9th—Connellsville Coke (f.o.b. ovens).

Furnace coke, prompt, $2 to $2.25 per ton.
Foundry coke, prompt, $3 to $3.50 per ton.

May 9th—Tin, straits, 50.25 cents.

Copper, Prime Lake, $50.25.
Electrolytic Copper, $15.60 to $15.70.
Copper wire, $16.75 to $17.
Lead, $4.35 to $4.40.
Spelter, $5.50 to $5.60.
Sheet zinc (f.o.b. smelter), $7.75.
Antimony, Cookson's, $8.80.
Aluminium, $26.50 to $26.62½.
Nickel, $40 to $45.

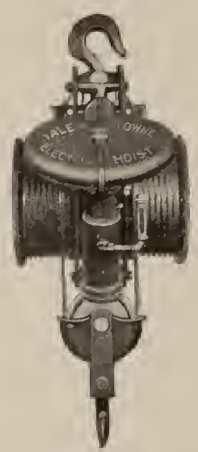
YALE

# Does a saving of $100 Interest You

## in your handling cost on an investment of $250

$100 a year is less than two dollars a week; it is less than thirty-five cents a day; it is less than one-fifth the daily wage of an unskilled laborer; it is less than five cents an hour.

Can you save five cents an hour by eliminating muscular effort; by lifting with a speed five times that of a hand hoist; by eliminating the delays of slow traveling crane service;



by enabling one man to lift, move and adjust twenty tons unaided.

The Yale & Towne Electric Hoist does all of these things, every day, the world over.

The saving is possible in every industry and in the smallest shops. It demands immediate action on your part. Write now for the Book of Hoists.

Highest Quality. Satisfaction in Use. Prompt Delivery. Keen Prices.

CABLES: "Ropery, Rutherglen." CODES: Western Union, A. B. C. (4th and 5th Editions), A.1., Liebers and Private.

# PROFESSIONAL DIRECTORY.

The very best advice that the publishers of the Canadian Mining Journal can give to intending purchasers of mining stock is to consult a responsible Mining Engineer BEFORE accepting the prospectus of the mining company that is offered them. We would also strongly advise those who possess properties that show signs of minerals not to hesitate to send samples and to consult a chemist or assaye Those who have claims and who require the services of a lawyer, with a thorough knowledge of Mining Law, should be very careful with whom they place their business.

# PROFESSIONAL : DIRECTORY.

CONTINUED FROM PRECEDING PAGE.

## ENGINEERS, METALLURGISTS AND GEOLOGISTS.

# ASSAYERS, CHEMISTS AND ORE TESTERS.

# BUYERS AND SELLERS OF METALS

# PROVINCE OF QUEBEC

## Department of Colonization, Mines, and Fisheries

*The chief minerals of the Province of Quebec are Asbestos, Chromite, Copper, Iron, Gold, Molybdenite, Phosphate, Mica, Graphite, Ornamental and Building Stone, Clays, Etc.*

The Mining Law gives absolute security of Title and is very favourable to the Prospector.

**MINERS' CERTIFICATES.** First of all, obtain a miner's certificate, from the Department in Quebec or from the nearest agent. The price of this certificate is $10.00, and it is valid until the first of January following. This certificate gives the right to prospect on public lands and on private lands, on which the mineral rights belong to the Crown.

The holder of the certificate may stake mining claims to the extent of 200 acres.

**WORKING CONDITIONS.** During the first six months following the staking of the claim, work on it must be performed to the extent of at least twenty-five days of eight hours.

**SIX MONTHS AFTER STAKING.** At the expiration of six months from the date of the staking, the prospector, to retain his rights, must take out a mining license.

**MINING LICENSE.** The mining license may cover 40 to 200 acres in unsurveyed territory. The price of this license is Fifty Cents an acre per year, and a fee of $10.00 on issue. It is valid for one year and is renewable on the same terms, on producing an affidavit that during the year work has been performed to the extent of at least twenty-five days labour on each forty acres.

**MINING CONCESSION.** Notwithstanding the above, a mining concession may be acquired at any time at the rate of $10 an acre for SUPERIOR METALS when more than 20 miles distant from a railway and $20 an acre when less than 20 miles.

For INFERIOR METALS the prices are $2.00 and $4.00 an acre respectively.

The attention of prospectors is specially called to the territory in the North-Western part of the Province of Quebec, north of the height of land, where important mineralized belts are known to exist.

**PROVINCIAL LABORATORY.** Special arrangements have been made with POLYTECHNIC SCHOOL of LAVAL UNIVERSITY, 228 ST. DENIS STREET, MONTREAL, for the determination, assays and analysis of minerals at very reduced rates for the benefit of miners and prospectors in the Province of Quebec. The well equipped laboratories of this institution and its trained chemists ensure results of undoubted integrity and reliability.

The Bureau of Mines at Quebec will give all the information desired in connection with the mines and mineral resources of the Province, on application addressed to

**THE HONORABLE THE MINISTER OF COLONIZATION, MINES, AND FISHERIES, QUEBEC.**

# The Minerals of Nova Scotia

The extensive area of mineral lands in Nova Scotia offers strong inducement for investment.

The principal minerals are:—Coal, iron, copper, gold, lead, silver, manganese, gypsum, barytes, tungsten, antimony, graphite, arsenic, mineral pigments, diatomaceous earth.

Enormous beds of gypsum of a very pure quality and frequently 100 feet in thickness are situated at the water's edge.

The Province contains numerous districts in which occur various varieties of iron ore practically at tide water and in touch with vast bodies of fluxes.

The Gold Fields of the Province cover an area of approximately 3,500 square miles. The gold is free milling and is from 870 to 970 fine.

Deposits of particularly high grade manganese ore occur at a number of different localities.

Tungsten-bearing ores of good quality have lately been discovered at several places and one mine has recently been opened up.

High-grade cement-making materials have been discovered in favorable situations for shipping.

Fuel is abundant, owing to the presence of 960 square miles of bituminous coal and 7,000,000 acres of woodland.

The available streams of Nova Scotia can supply at least 500,000 H. P., for industrial purposes.

Prospecting and Mining Rights are granted direct from the Crown on very favorable terms.

**Copies of the Mining Law, Mines Reports, Maps and Other Literature may be had free upon application to**

**HON. E. H. ARMSTRONG,**
**Commissioner of Public Works and Mines,**
**HALIFAX, N. S.**

# Ontario's Mining Lands

The Crown domain of the Province of Ontario contains an area of over 100,000,000 acres, a large part of which is comprised in geological formations known to carry valuable minerals, extending northward from the great lakes and westward from the Ottawa River to the Manitoba boundary.

Iron in large bodies of magnetite and hematite; copper in sulphide and native form; gold, mostly in free milling quartz; silver, native and in other forms; zincblende, galena, pyrite, mica, graphite, corundum, talc, marl, brick clay, building stones of all kinds and other useful minerals have been found in many places and are being worked at the present time.

In the famous Sudbury region Ontario possesses one of the two sources of the world's supply of nickel, and the known deposits of this metal are very large. The silver mines of the Cobalt district have astonished the world by their richness, and promising gold discoveries have recently been made in Porcupine Lake.

In the older parts of the Province, salt, petroleum and natural gas are important products. The cement and clay industries have a large output

The mining laws of Ontario are liberal, and the prices of mineral lands low.

The climate is unsurpassed, wood and water are plentiful, and in the summer season the prospector can go almost anywhere in a canoe.

The Canadian Pacific and other railways run through the entire mineral belt.

For reports of the Bureau of Mines, maps, mining laws, etc., apply to

**HON. W. H. HEARST,**

Minister of Lands, Forests and Mines,

**Toronto, Canada.**

| 1— 450 H.P. | " " | Acadia Coal Co., (in operation). |

The Siemens Companies undertake the complete electrical equipment of mines, collieries, factories, steel works, rolling mills, pulp and pape mills, and electrical plants of every description. Over 200 electrically driven hoisting engines have been installed with peak load from 500 H.P. to 5000 H.P.

Further information will be gladly furnished on request, and schemes prepared showing the economy of electric drive over steam winding.

## PROGRESS IN ALASKA

The report of the Mines Inspector for the Territory of Alaska has just been issued. The period covered is the fiscal year ended June 30, 1912.

The figures of production, we note, are carried only to the end of the calendar year 1911.

The total value of the mineral production of Alaska during the year 1911, was $20,650,005. By far the greater proportion of this was gold, which metal was mined to the value of nearly $17,000,000. The production of copper, however, has grown very markedly, its total value reaching the respectable sum of $3,666,584. The silver production was of relatively small value, and coal practically nothing. As a matter of fact, only 900 tons of coal were produced in Alaska, while practically 90,000 tons were purchased from British Columbia. The production of other minerals, such as marble, gypsum, tin, lead, etc., aggregated a value of $176,942.

Of the gold, approximately $12,500,000 was derived from placers, four and a quarter million from silicious ores, and $86,000 from copper ores. After reaching a maximum value of about $22,000,000 in the year 1906, the gold production of Alaska has fluctuated between a gross value of sixteen and twenty million dollars.

The silver production has gone up from about 50,000 ounces to a present output of nearly half a million ounces. While the copper production took a tremendous leap as between the years 1910 and 1911, in the former year, 1910, the production was four and a quarter million pounds, in 1912 the production was 27,267,871 pounds.

The Yukon basin is still the largest regional source of gold, with the Pacific Coast belt coming next, and the Seward Peninsula third.

It may be noted that the consumption of crude oil and naphtha has increased markedly in the last five years. In 1911 more than 18,000,000 gallons of crude oil, and a million and a quarter gallons of naphtha were shipped from other parts of the United States to Alaska.

It is gratifying to notice that the inspector reports the organization of mine rescue and first aid teams on Douglas Island. The work has also been taken up at a number of lode mines.

Considering all the conditions of work, the scale of wages is relatively low. The miners in the Fairbanks district get from $3.50 to $5.00 a day and board. At Nome the rates are higher, except during the winter. The ten-hour shift predominates. There is little, if any, labour trouble.

The extraordinary short sightedness of one United States federal administration has rendered it impossible to develop the Nome coal resources of Alaska. While this is in itself a vain and foolish thing, and is to be directly attributed to the insane overdoing of the conservation idea, yet it has inured to the benefit of British Columbia coal mines. Our readers may possibly remember that when Mr. Gifford Pinchot, the evangel of conservation, visited Alaska, the inhabitants were reported to have clothed themselves in the darkest mourning, and to have put all the flags at half mast.

Despite a short-sighted Federal Government, there appears to be reason to believe that Alaska will soon come into her own.

## THE LEAD BOUNTIES

The Budget speech of Honourable Mr. W. T. White contained the pleasing announcement that the Dominion lead bounties are to be continued. This, of course, will be excellent news for our friends in the West.

The huge surplus of $55,000,000 permits the present Government to deal liberally with such industries as legitimately need assistance.

In the course of the Honourable Mr. White's speech, he devoted considerable attention to the lead bounties. Provision for the payment of these bounties expires on June 30 of this year. The total appropriation set aside in 1903 was $6,000,000. On account of the high market price of lead not all of this was expended. In fact, there will be $600,000 unexpended on July 1st, 1913.

The proposal is to extend these bounties for five years, the necessary appropriation to include the unexpended $600,000. When the price of lead in the London markets exceeds 17 pounds, 8 shillings, 9 pence per ton, the bounty automatically is withdrawn until such time as the price falls.

It is a matter of record that since the inception of the bounties, the Canadian production of lead has increased from about 8,000,000 pounds to 34,000,000 pounds.

Incidentally, we may express our approval of the reduction of the tariff on cement. Slight as this reduction is, it will mean something to the Canadian purchaser.

## THE INTERNATIONAL GEOLOGICAL CONGRESS

The third circular of the International Geological Congress has just come to hand. This is to be the last general circular. Further official information will be sent only to actual members of the Congress. As applications to join the excursion are exceeding all expectations, it is decidedly necessary that those who have not applied for membership do so at once. This particularly applies to appointed delegates who have not yet sent in applications, nor designated the excursions in which they desire to participate.

regards excursions. One in particular, excursion A9, will start from Kingston. Another excursion, C1, will be modified so as to eliminate the visit to Munson on Sept. 3. Still another change in excursions CI, and CII will time the visit to the Sudbury nickel copper deposits for the beginning, and not the end of these excursions.

As matters stand now, the date for leaving Montreal for Quebec and the Maritime Provinces is fixed for Sunday, July 13; for leaving Montreal for Sudbury, Cobalt, and Porcupine, Wednesday, July 23; for leaving Montreal for Haliburton and Bancroft, July 24; and the opening day is set for Thursday, Aug. 7th, in Toronto.

Members of the Congress may secure single tickets at half the lowest, one way, first-class fare. Round trip tickets may be secured at the price of the lowest, one-way, first-class fare, provided the same route be followed going and returning. Tickets will be used from July 15th to Oct. 31, 1913, but cannot be used or purchased after the latter date. These arrangements apply only to professional members, non-professional members are, however, granted almost equivalent privileges.

Since the fee for membership is only $5.00, all those desiring to join any of the excursions should apply at once to the secretary, Victoria Museum, Ottawa.

It may be noted here, that the monograph on the coal resources of the world is to be published in the form of three, not two, quarto volumes, and a folio atlas.

All possible arrangements have been made for the convenience of excursionists. On another page will be found a reproduction of part of the third official circular.

## A SUGGESTION FROM THE WEST

The British Columbia Mining Association has placed itself on record as appreciating highly the work of Mr. R. F. Green, M.P. for Kootenay, B.C. To his hard work, and to the clear-sightedness of the Honourable Mr. W. T. White, is attributed the continuance of the lead bonus.

At the same meeting the Ottawa Government was again strongly requested to create a separate Portfolio of Mines at Ottawa. To this request was joined the suggestion that Mr. Green be appointed Minister of Mines.

While the suggestion of creating a separate Portfolio of Mines is one in which we thoroughly concur, and one that we have been urging for some years, it is our opinion that the British Columbia Mining Association has not acted wisely in beclouding the issue by submitting the name of Mr. Green.

Mr. Green's merits or demerits have nothing to do with the case. The chief point is to convince the government that a Portfolio of Mines is a necessity. After that the matter of selecting the Minister will take care of itself.

## UNITED STATES COAL MINE ACCIDENTS

The monthly statements of coal mine accidents in the United States show a distinct improvement for the months of January and February, 1913. as compared with the corresponding months for the previous year. In January, 1912, there were 243 fatalities in and about coal mines. In February, 1912, there were 207. In January and February of this year, there were respectively 213 and 197. Thus the total for the two first months of this year is less by 40 than the total for the first two months of last year.

It is apparent that since the very inception of the vigorous campaign for installing life saving apparatus, the deaths per thousand men employed have steadily decreased.

For 1912 the figure was 3.15; for 1909 it was 4. Putting it in another way, for each death 233,000 tons of coal were produced in 1912, while for each death in 1909 only 173,000 tons were produced. Unless some disaster of extraordinary magnitude should occur this year the precautionary measures introduced by the United States Bureau of Mines will certainly have demonstrated their value.

## EDITORIAL NOTES

The price of silver is holding most satisfactorily. At the Hollinger mine, Porcupine, the hydro-electric power is again available.

The Crow's Nest Pass Coal Co. reports a decidedly profitable year for 1912. According to their statement net profits of $471,454 are shown.

The Lucky Jim zinc mine of British Columbia has hardly lived up to its name. At present it is reported to be in very serious difficulty owing to an accumulation of debts.

It is reported that the Quebec magnesia deposits have been taken over by a new concern having affiliations with United States investors. The crude material apparently is to be worked up into finished product at Newark, New Jersey.

## BOOK REVIEW

**AIR COMPRESSION AND TRANSMISSION—By H. J. Thorkelson—Associate Professor Steam and Gas Engineering, University of Wisconsin—207 pages—Illustrated with many diagrams and line cuts—Price $2.00—Published by the McGraw-Hill Book Co., 239 West 39th St., New York, 1913—For sale by The Canadian Mining Journal, Toronto.**

There already have been published a number of descriptive text books dealing with the mechanical principles and the actual use of air compression and transmission. In most of these books the attempt has been made to cover the whole subject. Mr. Thorkelson has confined himself to the methods of calculation, whereby the efficiency of any given system may be determined, or the needs of any given mine or other establishment, measured.

After a brief prefatory note in which the author points out that railway men were among the first to appreciate the uses of compressed air in shop and structure work, and that compressed air is used in over sixty different industries at present, the general text commences.

Chapter I. deals with the characteristics of air; Chapter II. with fundamental definitions; Chapter III. with the characteristic and energy equations for air; Chapter IV. with graphical diagrams; Chapter V. with air at pressures below the atmosphere; Chapter V., as indicated by its title, takes up vacuum pumps, the Sprengle air pump, the measurement of vacuums, condenser pumps, etc. The next Chapter has to do with air at low pressures. Under this heading come cupolas, ventilation, measurement of draft, fan efficiency, rotary blowing machines, and other cognate subjects. Chapter VII. is a discussion of piston compressors. Efficiencies and energy compensation form the subject matter of Chapter VIII. Chapter IX. is entitled Multistage Compression. Chapter X. is devoted to the mechanical details of piston air compressors. Chapter XI. touches on the design of turbo-compressors. Chapter XII. which is one of the most interesting in the book, compares the various types of hydraulic air compressors and the general principles involved. We note that the large Cobalt installation is not mentioned here. The effect of altitude on capacity and on power is the topic of Chapter XIII. Chapter XIV. touches the design of receivers, and the measurement and transmission of compressed air.

In the concluding Chapter the selection of compressors and matters pertaining to their general efficiency, are discussed. Three appendices, one a table of Common Logarithms, one a table of Naperian Logarithms, and one a short treatise on Hygrometric, conclude the volume.

### REMOVAL NOTICE.

We wish to notify our readers that the offices of the Canadian Mining Journal have been removed from 10 Adelaide Street East, to the second storey of 44-46 Lombard Street, one-half block north, and two blocks east. The present offices will be much more commodious than those we have left.

The Canadian Mining Journal in its new quarters will possess the distinct advantage of having direct access to its own printing plant, which is housed in the basement of the same building. This fact we would request our readers to bear in mind. The plant referred to, is large and completely equipped.

# THE "DE RE METALLICA" OF GEORGIUS AGRICOLA*

## A REVIEW

(Continued from April 1st Issue.)

The methods of staking mining lands in Germany during the sixteenth century, and the officials that were to be approached, are dealt with in Book IV. The Bergmeister, having satisfied himself as to the discoverer's identity, awarded the "head meer" to him, and the remaining "meers" in order to each successive applicant. The head meer, staked on a fissure vein, measured 42 fathoms by 7 wide, while the ordinary meer was 28 by 7. For other classes of deposits other units obtained. Many restrictions were imposed upon individual operators, and there was quite as much red tape as one finds to-day. These, the duties of the mine manager, the collection of tithes, Agricola explains with care and precision. It appears that in those days the day was divided into three seven-hour shifts—morning, noon, and night. "The Bergmeister" it is noted. "does not allow this third shift to be imposed upon the workmen unless necessity demands it." Truly the height of consideration! When, however, the men were forced to work the third shift Agricola remarks that "they keep their vigil by the night lamps, and... .....they lighten their long and arduous labours by singing, which is neither wholly untrained nor unpleasing." In some places miners were not allowed to work through two successive shifts, in other places the only limiting factor was his own power of endurance. Saturdays and Sundays were regular holidays—Saturdays devoted to shopping and Sundays to "holy things."

The practical work of mining and the art of surveying from the subject-matter of Book V. The advice given as to sinking shafts is that, first, a separate shaft house be built wherein is placed the windlass. Here, also, are kept the iron tools and other mining implements. It is further recommended that adjoining this structure a dwelling be constructed for the mine foreman and workmen. In a quite casual manner Agricola mentions that "the ore and other things which are dug out" are also to be stored in this edifice. Here is a charming sidelight: "Although some persons build only one house, yet because sometimes boys and other living things fall into the shafts, most miners deliberately place one house apart from the other, or at least separate them by a wall."

General instructions follow and illuminating definitions shine like gems throughout. "A tunnel," says Agricola "is a subterranean ditch driven lengthwise and is nearly twice as high as it is broad, and wide enough that workmen and others may be able to pass and carry their loads. It is usually one and a quarter fathoms high, while its width is about three and three-quarters feet......Each miner sits upon small boards fixed securely from the footwall to the hanging wall." We wonder if it would conduce to efficiency and peace of mind were modern workmen required to work in a "subterranean ditch," three and three-quarters feet wide.

Our mediaeval friend had evidently paid much attention to the character and modes of occurrence of ore in advising the miner where and how to sink on his vein. He lays special emphasis upon the functions of stringers and main veins, and upon vein intersections generally. He then discusses with some elaboration the actual relationship of characteristic minerals and metals—a strangely interesting bit of empirical paragenesis. Here are typical statements: "A vein which contains a larger proportion of silver than gold is rarely found to be a rich one......The solidified juices, azure, chrysocolla, orpiment and realgar, also frequently contain gold." As to indications of valuable metals Agricola explains among other things that if the miner comes across "dry earths which contain native or *rudis* metal, that is a good indication; if he comes across yellow, red, black. or some other extraordinary earth, though it is devoid of mineral, it is not a bad indication." Schist of a bluish or blackish colour, and limestone of any colour whatsoever, are good indications of silver. Bismuth and antimony are described as special indications of silver; orpiment as special indication of gold; verdigris, *melanteria,* and vitriol, are taken as indicating copper. It is mentioned that bismuth was called by miners "the roof of silver."

Evently extralateral rights did not obtain in those days, as witness the following: "If it [the vein] descends vertically into the earth, the benefit belongs to that mine in which it is seen first of all; if inclined it benefits the other neighbouring mines. As a result the miner who is not ignorant of geometry can calculate from the other mines the depth at which...... the vein bearing rich metal will wind its way through the rocks into his mine."

The modes of extracting the vein matter are now elucidated. As Agricola wrote before the introduction of explosives into the mine, the principal method of extracting hard ore was by means of fire. A heap of dried logs was placed against the rock and ignited. In many cases this process was not only exceedingly tedious, but it caused distress in neighbouring mines which happened to be connected with that in which fire was being used. Hence permission had to be asked of the owners of neighbouring mines and in the case of arsenical, anitimonial, or sulphurous ores the permission of the "Bergmeister" was necessary. After long calcination the ore was dislodged by means of crowbars and hammers. It was always to be hand sorted in the mine, where fire was not necessary or not permitted the miners had perforce to rely upon purely mechanical means.

The practice of timbering was not, in Agricola's time, as crude as one might expect. Pumping was usually accomplished by hand or by horse power, although mechanical appliances were sometimes used. Surveying, to which the latter part of Book V. is devoted, was practised only in its simplest form. A knowledge of the rudiments of geometry with a touch of trigonometry was the basis of the art.

The sixth book contains descriptions of the tools, vessels and mechanical devices used in the mines. Winding, ventilating and pumping machinery, drills, hammers, picks, are clearly described by text and wood cuts. The barrows and trucks in vogue were exceedingly substantial in design. For baling water small and large wooden buckets fed by means of cumbrous wooden dippers were filled and hoisted by hand to the

* Georgius Agricola De Re Metallica.—Translated from the first Latin edition of 1556 with Biographical Introduction, Annotations, etc., by Herbert Clark Hoover and Lou Henry Hoover.—Published for the Translators by the Mining Magazine, London.—For sale by the Canadian Mining Journal, Toronto, Canada.

surface. These were often replaced by water bags made of ox-hide. "When these water bags have undergone much wear and use, first the hair comes off them and they become bald and shiny. After this they become torn."

The windlass of Agricola's time was essentially a duplicate of many that are to be seen on small prospects to-day. For the deeper shafts, however, a three-man windlass was used, on the barrel of which was fixed a wheel of large diameter which served the purpose of a fly-wheel. While one man turned the crank two other men at the opposite end of the windlass worked upon four straight levers passing through the end of the barrow. "All windlass workers," says Agricola, "whatsoever kind of a machine they may turn, are necessarily robust that they can sustain such great toil."

A third kind of machine was designed to hoist ore from the extraordinary depth of one hundred and eighty feet! This was a vertical two-man hoist. The horse-whim, both single and double, was also in vogue. One illustration shows the rider sitting luxuriously on a cross-beam driving two horses. For transporting the ore from the mine to the furnace all kinds of methods were resorted to. Horses drew rude sledges filled with ore. Pack teams of dogs were common. Where the topography would permit the ore was raw-hided or merely rolled down the mountains. Perhaps the most picturesque method is thus outlined:—Two or three sacks of ore were placed on a small sledge higher in front and lower at the back. "Sitting on these sacks, not without risk of his life, the bold driver guides the sledge as it rushes down the mountain into the valley, with a stick which he carries in his hand."

Pumping was accomplished by various means. Men worked in tread wheels running endless bucket elevators. Hand pumping in various ingenious forms was practised. For greater depths water power was ingeniously applied with sumps established at the different levels. It would be quite impossible to touch upon the quaint designs in use. Suffice it to say every kind of available power was utilized. Not only were men and horses called upon to do their duty, but goats were frequently used in the tread mill.

Rude blowers, fans, and bellows, worked by hand or by horse power provided ventilation or draughts, were induced by ventilating shafts. Water power also was called into service. Means were sometimes taken by structures superimposed on the shaft mouth to catch the wind and divert it down the shaft.

Towards the conclusion of Book VI. Agricola indulges in a little moralizing. Touching on poisonous gases, he remarks on the danger of arsenical poisoning, and mentions that men even in the act of climbing ladders fell back into the shaft when the poison overtakes them. "At such times, no one should descend into the mine or into the neighbouring mines, or if he is in them he should come out quickly." Foremen are adjured to look carefully to the condition of their ladders and the men similarly are advised not to "fall through their own carelessness." Allusion is made to a venomous ant, not found in the mines of which Agricola writes, but in Sardinia. "It creeps unobserved and brings destruction upon those who imprudently sit on it. But......springs of warm and salubrious waters gush out in certain places, which neutralize the venom inserted by the ants." As if to compensate for the absence of these destructive insects Agricola continues. "In some of our mines, however, though in very few, there are other pernicious pests. These are demons of ferocious aspect.......Demons of this kind are expelled and put to flight by prayer and fasting." As subordinate in importance to these diabolical intruders, the chief causes for abandoning mines were barrenness, over much water, noxious gases, falls of rock, and "military operations."

(To be Continued).

---

## SILVER VEINS IN SOUTH LORRAIN, ONT.

By J. B. TYRRELL.

In the district of South Lorrain, lying sixteen miles south-east of Cobalt, several rich silver-bearing veins have been opened up and worked to a greater or less extent, and as these veins are similar in character and appearance to those in the older and better known Cobalt camp a brief notice of one, at least, of their peculiarities may be interesting to your readers.

As in the country around Cobalt, the rocks consist of Keewatin greenstones with characteristic intrusive dykes of lamprophyre, etc.; conglomerates which have been designated by the geologists of the Ontario Bureau of Mines as of Huronian age, and great intrusive masses of coarse diabase.

Looking at the map published by the Ontario Bureau of Mines it will be noticed that the western edge of the intrusive diabase runs almost in a straight line from north to south. As a general rule the veins, as far as I have seen them, appear to be near this western edge of the diabase, either to the east of it in the diabase itself or to the west of it in the Keewatin greenstones, for in this district the conglomerates do not appear to have been attractive to the silver-bearing solutions.

I do not know whether the diabase is here in the form of a sill as it is in Cobalt or not. In this latter camp it is now generally recognized that the silver-bearing veins have been formed by the diabase, or rather that they have been in the nature of end products deposited around the periphery of the diabase after the main intrusion had ceased and the rock had cooled below the temperature of solidification. In this camp also the upper and lower surfaces of the diabase sill, or intrusive mass, approximate more or less closely to the horizontal and the fissures caused by the cooling of the rock have, as a rule, been normal to these horizontal surfaces and have therefore approximated more or less closely to the vertical. After the fissures were formed, either in the solidified diabase, or in the contiguous rock, whatever it might happen to be, the silver-bearing solutions flowed into them and filled the fissures that extended up and down from the diabase and formed veins in these fissures.

While emanations from the diabase gave rise to the Cobalt silver veins, it was not always necessary that the wider parts of the veins should be directly in contact with the originating rock, for the solutions bearing the vein-forming material would circulate in any open fissures that happened to be at all within reach of, or connected with, the diabase.

Now in South Lorrain the conditions are very similar to those in Cobalt as briefly outlined above, but, in some instances at all events, the attitude of the plane of contact of the western edge of the diabase and the contiguous rock, which in this case is greenstone, is not horizontal, but nearly vertical, and many of the principal veins run east and west, normal to this plane of contact.

As at Cobalt, the diabase contact is the controlling factor, but instead of the veins running up and down from a horizontal contact, they here run outwards, from and at right angles to a vertical contact, and therefore a horizontal section of a vein, as seen on the surface here, represents what might be looked for in a vertical section in Cobalt. The rich ore-bodies, where they occur, are not found directly at the diabase contact, but at some little distance away from it either in the diabase or in the greenstone, beyond which, as the vein is traced farther and farther from the contact, it becomes narrower and breaks up into veinlets which run out and disappear in the adjoining rock.

Whether the greenstone-diabase contact on the western border of the diabase in South Lorrain will continue downwards vertically, or at a high angle, for any great distance or not is as yet uncertain; but if the contact should maintain its vertical attitude to considerable depths it would seem not improbable that these veins and ore-bodies, which have been formed by emanations from the diabase, might have their greatest extension in a vertical direction, in conformity with the attitude of the plane of contact, rather than in a horizontal direction as is the case with the ore-bodies at Cobalt and in its immediate vicinity.

# MINING AND THE CANADIAN NORTHERN RAILWAY

(Written for the Canadian Mining Journal.)

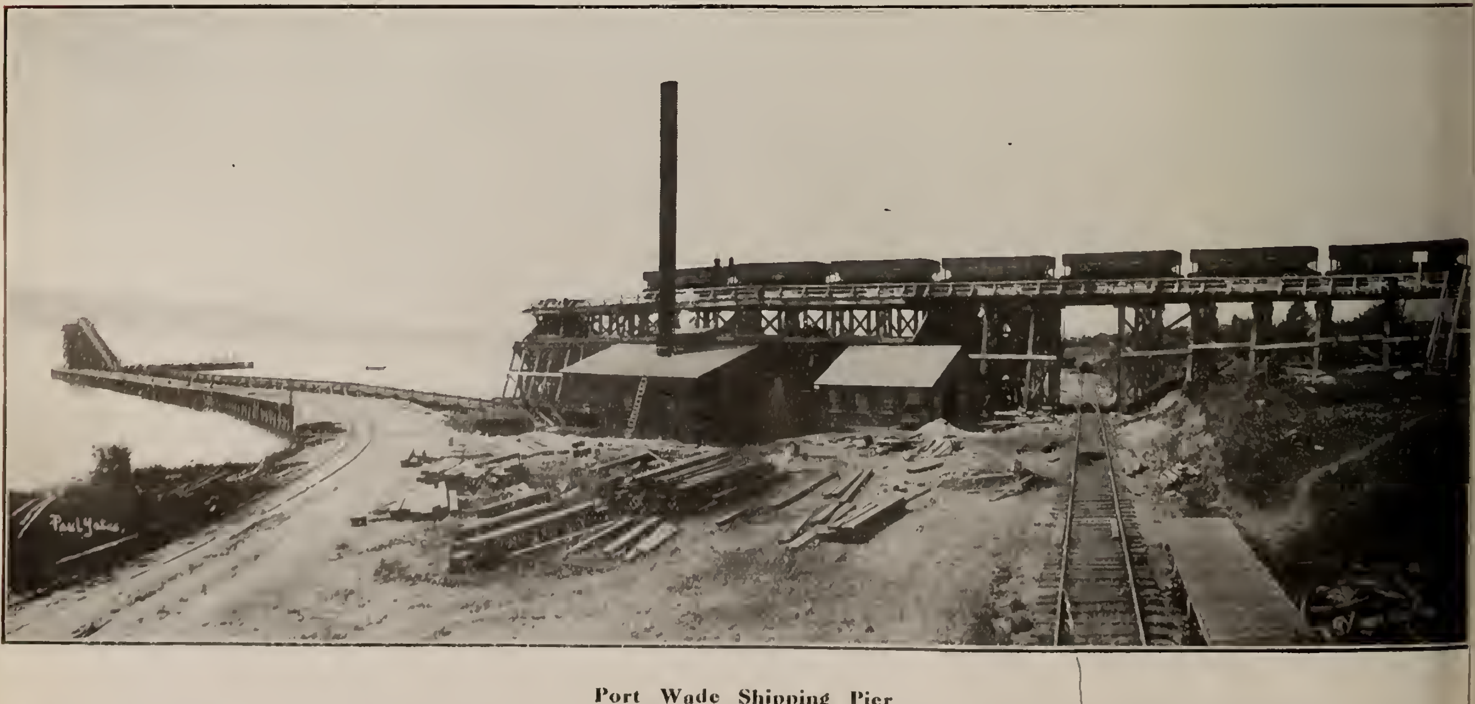
Except for fortunate accidents the general politics pursued by Canadian railway corporations have not untill the last decade or so included any clear cut attitude towards mining. In one sense this is not strange, as our railway magnates have been far too deeply involved in actual construction to attend to anything but immediate necessities. Yet it is beyond argument that had our transportation corporations followed more closely the mining development of the country they would have strengthened their own position decidedly, and would have hastened the inevitable development of mining and other allied industries.

One has but to look over the border at a few of the large railway concerns in the United States to realize what the mine yields in the way of freight traffic. The vast volume of freight that accures to the railways from the coal mines, iron mines, copper mines, and from other mines of all kinds, and the correspondingly large return traffic from the smelters, must be recognized as one of the vital factors in the history of transportation, and in fact, in the prosperity of the whole country.

No large railway can subsist on one class of freight traffic. No single industry can be depended upon to yield such a bulk of freight as can mining. On the other hand, the farmer, the manufacturer, and the merchant invariably follow in the wake of the miner. In other words, a country that is opened up for mining purposes will also be opened up for farming and the general activities of civilization. It is a fact that there are few mining regions in Canada that are not within easy reach of good areable land. Thus the miner, as a pioneer, opens up the road for, first, the agricultural industry, and then for others. Communities are established and traffic of all kinds is created.

Whilst in a great many instances the discovery of important ore deposits in Canada has been the accidental result of railway construction, yet in more instances, discovered mines have had to await for years the construction of the railway This is too obvions a truth to require specific illustration

The following series of articles has to do with the relation of mining to the growth of one large railway corporation; namely, the Canadian Northern Railway. The Canadian Northern has from its inception striven to give direct recognition to the mining industry. This, of course, has not been done in any altruistic spirit. The



Port Wade Shipping Pier

Eastern Lines of Canadian Northern Railway company has been keenly aware of the revenue value of ore tonnage, and consequently has deliberately located its lines to pre-empt as much mining business as possible. The object has ever been, therefore, to accelerate mineral production.

Over the country tapped not only by the main lines, but especially by many of the branch lines of the Canadian Northern, there are practically numberless mineral deposits, many of which are of proved commercial value, and many more of which hold out promise to the prospector and to the investor.

In this short series of articles it will be possible to indicate only in the most general way, the geological character and mineral occurrences throughout the Canadian territories traversed by the Canadian Northern. It will be most convenient to start from the East and work gradually through to the West.

First, however, it may be well to make a few general remarks concerning the relation of transportation to mining Of all the freight handled by the Canadian Northern Railway, at least 33 per cent. is contributed directly by the mining industry. This does not include many metallurgical products, but is made up almost entirely of the direct products of the mine. In the United States the figures are proportionately higher. It gives some idea of how far we shall have to grow to realize that the mining industries of the States contribute nearly 60 per cent. of the freight moved there. Until some such figure is attained in Canada we shall not have attained our normal growth.

Unlike most of the products of the farm, or even of the forest, the mine products that form a source of freight are produced the whole year round Hence their importance to any given railway is hardly to be exaggerated .

Starting then on the west coast of Cape Breton Island, we find the Inverness branch of the Canadian Northern tapping a rich coal region The Inverness colliery itself, which is the present northerly terminal of the line, produces about 300,000 tons of high grade steam coal per year. A large portion of the country, both north and south of Inverness proper, is rich in coal veins. Here is the first instance of what has been mentioned above. The Inverness branch was built primarily to develop the coal fields of the county.

To the north of Inverness, near the north-western extremity of the Island of Cape Breton, there are extensive, though undeveloped, deposits of gold bearing mispickel and copper. There are also commercial deposits of barite, and large bodies of excellent gypsum. All of this region is tributary to the Inverness branch, the southern terminal of which is at Port Tupper on the Straits of Canso.

Beginning at Halifax and running in a south-westerly direction, the Halifax and South Western Railway runs along the Atlantic shore round the southernmost heel of Nova Scotia, to the flourishing city of Yarmouth. Many square miles of the country thus cut are rich in minerals. For instance, at Chester Basin, a point 40 miles from Halifax, small though rich gold veins have been worked for a number of years. Running inland at right angles to the line, a drive of an hour and a half or so, takes one into a region where not only are tin and tungsten minerals known to exist, but manganese in the form of pyrolusite, is being worked to advantage. Along the shore in the vicinity of Liverpool large flake mica has been found, although never as far as is known, worked. In the County of Yarmouth itself the Cambrian gold measures are extensive. Within a comparatively short distance of Middleton (see map) are the enormous Torbrooke and Nictaux iron deposits, both hematite and magnetite which are now being worked by the Canada Iron Corporation. Large quantities of these ores are mined, milled, and shipped as concentrates. The milling process is simple as it consists essentially in crushing and jigging, yet the ore is brought up to a high tenor. As this ore is phosphatic it makes an admirable mixture for burdening the blast furnace for foundry pig. Here again it may be noted that the Canadian Northern constructed the branch line from Middleton to Port Wade, a shipping point on the Bay of Fundy. (See photograph).

The region thus tapped by the Canadian Northern in south-western Nova Scotia is exceedingly rich in gypsum and limestone, and in addition to the Nictaux and Torbrooke iron deposits, has promise of other considerable iron ore bodies.

One great advantage of the Nova Scotian lines is their accessibility from tide water. The inland shipper of heavy mineral products is often placed at a disadvantage owing to the excessive rail hauls. All the distances in Nova Scotia are short, and the harbour facilities at such points as Halifax, Liverpool, Yarmouth, and Port Wade are excellent. Not only is the Canadian St. Lawrence market made available, but the whole Atlantic coast of the United States is directly accessible.

As to the proposed line shown in dots from Quebec through to Pugwash, the general statement may be vouchsafed that the greater proportion of the area traversed is rich in natural resources. Near Fredericton, for instance, antimony veins have been worked. In the vicinity of Moncton enormously rich natural gas deposits are being exploited and developed, and extensive oil shale bodies are soon to form the basis of a huge industry, an industry that will have countless ramifications.

In process of time, iron, copper, and possibly gold and tin deposits will be opened in the New Brunswick section. So far very little prospecting of any kind has been done. Nevertheless there are large positive possibilities that may be mentioned. These include the quarrying of building stones (and this applies equally to Nova Scotia), gypsum, barytes, and limestone. The distribution of fertilizer (ammonium sulphate), from the works that are to be established on the oil shale deposits will mean much. Not least important will be the increasing traffic in the brick manufacturing industry. South-eastern New Brunswick is rich in brick clay. All of these commodities will in time assuredly bring a large amount of traffic to the line. Taking, for instance, the case of gypsum, we discover that of the 450,000 tons quarried in Nova Scotia and New Brunswick the great bulk is shipped crude to the United States, not more than 20,000 tons per annum being manufactured into gypsum products in Nova Scotia. Much of this crude material after being calcined and ground is shipped back from the States into Canada against a substantial duty.

Not only is Nova Scotia third in the value of her annual production of minerals, but the Province is by far and away the most important producer of coal in the Dominion. The annual output of coal is about six and one-half million tons, about 50 per cent. of Canada's whole output.

The following table gives specific figures for the year ending September 30, 1912.

## NOVA SCOTIA MINERAL PRODUCTION.

Year ended September 30th, 1912:

| Mineral. | Quantity 1911. | Quantity 1912. |
|---|---|---|
| Coal raised (gross tons) ....... | 6,208,444 | 6,802,997 |
| *Iron ore (net tons) .......... | 53,595 | none |
| Pig iron made (net tons) ...... | 397,615 | 411,388 |
| Steel ingots made (net tons) ... | 438,922 | 461,392 |
| Limestone quarried (net tons).. | 525,286 | 473,067 |
| Coke made (net tons) ........ | 545,619 | 603,372 |
| Gypsum quarried (net tons)... | 333,358 | 280,000 |
| Building stone quarried (net tons)................... | 11,226 | 11,644 |
| Bricks made (number) ........ | 23,273,700 | 22,348,486 |
| Drain pipe and tile made (feet). | 1,431,761 | 984,922 |
| Grindstones quarried (net tons) | 380 | 400 |
| Gold bearing ore mined (net tons | 18,320 | 15,868 |
| Gold produced (ounces) ....... | 8,389 | 4,948 |
| Manganese ore (net tons) ...... | 150 | 233 |
| Antimony concentrates (net tons) | 191 | none |
| Moulding sand (net tons) ...... | 380 | 1,190 |
| Tungsten concentrates (net tons) | none | 14 |
| Sulphate of Ammonia (gross tons).................... | 3,971 | 5,213 |
| Barytes .................... | | 974 |

*Iron ore imported 1910-11, 853,904. 1911-12, 880,904 net tons. Operations at Torbrook mill not up to capacity.

The value of the annual mineral production of the Province divided by the number of square miles of territory is about $1,100 per square miles. This works out at nearly $50.00 per capita.

### GEOLOGY.

The geology of the regions dealt with in this article can be best described by quoting from a monograph written by Dr. G. A. Young, and published by the Geological Survey of Canada. The following paragraphs are made up of isolated sentences from Dr. Young's text.

The southeastern portion of Quebec, together with the Maritime Provinces, form the northeastern extension of the Appalachian Mountain system. The Appalachian region is characterized by formations, ranging from pre-Cambrian to Carboniferous, that are disturbed and thrown into a succession of folds. Important deposits of coal, iron, and gold are mined in Nova Scotia. Its coal resources have been estimated by the Hon. R. Drummond to be six billion tons.

The gold bearing series of Nova Scotia, together with great instrusive measures of later granites, occupy the whole Atlantic coast of the peninsula extending in the southwest, almost completely across it. and underlying in all an area of some six or seven thousand square miles. This series, consisting of a lower division comprised largely of quartzite. and of an upper one, mainly of dark slates, has yielded a section of over 25,000 feet of sediments. Cutting the sediments are large batholitic bodies of granite of a later age, possibly late Devonian. Along the axes of folding, within the lower quartzite division, is a widespread system of veins of quartz, often gold-bearing. The Carboniferous strata of the Maritime Provinces within which occur the prolific coal seams of Nova Scotia, are of immense volume. They occur along the western portions of Cape Breton, skirting hills of crystalline pre-Cambrian rocks, or penetrating them along the courses of old pre-Carboniferous bays and valleys. Near the Sydney coal fields of Cape Breton there is a combined section of about 13,000 feet, and along the Nova Scotian shores of the Bay of Fundy, the famous Joggins section has a thickness of above 14,500 feet in which over 70 coal seams are exposed. The Carboniferous sediments in New Brunswick occupy about 10,000 square miles, forming an area triangular in shape, bordering the eastern coast and contracting inland between the two elevated districts of the Province. The Carboniferous and overlying measures extend eastward into Nova Scotia, occupying much of the country north of the Bay of Mines, and reaching into Cape Breton.

In the Eastern Townships of Quebec, the rocks of the pre-Cambrian areas appear to be almost entirely volcanic rocks, chiefly basic varieties. In the Gaspé peninsula, the corresponding rocks include other forms of the nature of granites, as well as acid volcanics and possibly sediments. The same is true in the regions in northern New Brunswick, while in southern New Brunswick and Cape Breton, besides large volumes of granitic and gneissic rocks, variously altered acid and basic volcanics are common, and there also occur masses of crystalline limestone as well as schistose rocks of possibly sedimentary origin. In the northeastern portion of the peinsula of Nova Scotia are considerable districts occupied by greatly disturbed formations probably of Ordovician age, consisting of sediments accompanied by large volumes of igneous rocks, some of which may represent the product's of contemporaneous volcanoes. In New Brunswick, Ordovician beds partly occupy the broken hilly country stretching northeasterly through the province to Chaleur Bay. In this region, the beds of this system consists of shales and sandstones, or their altered equivalents, often penetrated by large bodies of granite and other igneous rocks. Throughout western and northwestern New Brunswick and the Gaspé peninsula generally, large tracts are floored by great volumes of shales, often Calcareous) sandstones, and limestones of Silurian age, now usually highly folded and faulted. With these beds occur many varicties of igneous rocks, some of which represent the products of contemporaneous volcanoes. In Nova Scotia the Silurian strata are largely confined to the northeastern portion of the province, and at one locality on the shores of Northumberland straits there isa nearly complete section of the whole system represented by about 3,000 feet of sediments. Early Devonian calcarious beds occur in Nova Scotia. In southwestern New Brunswick great volumes of argillaceous and arenaceous strata occur. These have also been assigned to the Devonian. The same conditions are duplicated in Nova Scotia, where at one place occur strata containing tuff-like beds indicative of contemporaneous volcanoes.

---

Mr. G. B. Wilson is manager of a marble quarry at Marblehead, on the C.P.R. Company's railway line from the head of Kootenay Lake to Trout Lake, B.C.

Mr. J. B. Sword, who has been in Victoria, B.C., during recent months, with associates has again got control of some iron ore claims on Louise Island of the Queen Charlotte group.

Mr. L. B. Reynolds, of Nelson, B.C., is stated by the Daily News to have been ill with typhoid fever at the Hart private hospital, Roxbury, Massachusetts. Mr. Reynolds came East in February, intending to take a trip to Europe. He was at the annual meeting of the Canadian Mining Institute in March.

# CONGRESS GEOLOGIQUE INTERNATIONAL

XIITH. Session, Canada, 1913. Third Circular. Special Notices.

### Third and Last Circular.

This is the last general circular. Any further information will be sent only to members of the Congress.

Copies of the second circular of the Twelfth International Geological Congress can be obtained from the secretary of any geological society, geological survey, mining society, or from the secretary, Twelfth International Geological Congress, Victoria Memorial Museum, Ottawa, Canada.

### Applications to Join Excursions.

Applications to join excursions are being received at a much more rapid rate than was anticipated, therefore, those desiring to join excursions should make no further delay in sending their applications.

### Delegates.

Many delegates appointed by various universities and societies have not yet sent in applications for membership nor for participation in excursions. As applications are being received at a rapid rate, delegates are particularly requested to apply at the earliest possible moment for such reservations as they require.

### Papers and Proposals.

Every endeavour will be made to print in advance of the meeting such contributions as are received up to June 1st. Though every effort will be made to print contributions received after this date, it is not probable that this will be possible. The attention of authors is respectfully drawn to regulations 7a to 7h, page 6, second circular.

### Price of Guide Books.

The price of guide books to persons who are not members of the Congress is seven and one-half dollars for the complete set, the price to members is two and one-half dollars for the complete set. Single guide books will not be sold and only one set at the price of two and one-half dollars will be sold to each member.

### Coal Resources of the World.

The monograph on the coal resources of the world will be published in the form of three (not two as originally intimated) quarto volumes and a folio atlas, the price of which to persons who are not members of the Congress will be twenty-five dollars per set. Members of the Congress have the privilege of buying one set at the price of twenty dollars net provided their orders reach the publishers, Messrs. Morang and Company, Limited, Toronto, or the Secretary of the Congress on or before August 15th, 1913.

### Remittances.

In case it is not convenient to remit by post office money order, drafts drawn on the Royal Bank of Canada in Ottawa, will be accepted Remittances should be payable to the International Geological Congress and for the exact amount in Canadian dollars and cents, at par, at Ottawa. Cheques can not be accepted.

### Payments for Excursions.

The final payments by those participating in excursions should be made in advance of initial date of excursions and as soon as possible after the arrival in Canada of the member or delegate.

### Headquarters During Session at Toronto.

The headquarters will be at the University of Toronto where there will be a branch post office open at all hours and at which registered mail may be received or despatched, money orders sent or cashed, etc. A bank will be established at which money may be exchanged. A typewriting service will be maintained, also a telephone service and messenger service. Railway and steamship agents will also be in attendance.

A restaurant service providing luncheon in the middle of the day will be arranged.

## CHANGES AND ADDITIONS TO EXCURSIONS

**Excursion A.1.**—While at Perce on July 16th, a tablet will be unveiled in memory of the late Sir William Logan, the founder and first director of the Geological Survey of Canada. Sir William Logan's name is familiar to all students of geology, and his interpretation of the structure of the Gaspe peninsula was one of his earliest as well as one of his most remarkable achievements.

**Excursion A.9.**—This excursion starts from Kingston which is at the foot of Lake Ontario and the head of St. Lawrence River, about midway between Montreal and Toronto. Kingston can be reached in a few hours by the Grand Trunk Railway from either Montreal or Toronto or by boat from either place. The combined water and rail route from Montreal as far as Prescott over the Grand Trunk Railway, and from Prescott to Kingston by boat through the Thousand Islands, is especially attractive.

**Excursion C.1.**—It was announced in the Second Circular that a visit would be paid on September 3rd to the Dinosaurian bone beds near Munson but it is probable that this part of the excursion will have to be cancelled because the railway line to this point may not be completed. If, however, any individuals are very desirous of seeing these deposits and if they will so advise the secretary, an endeavour will be made to arrange for a visit to the locality.

**Excursions C.1. and C.2.**—A change will be made in the time table of excursion C.1. so that both excursions C.1 and C.2 may meet in Victoria, British Columbia, on August 26th. In consequence of this change the Sudbury nickel-copper deposits will be visited by excursion C.1 at the end of the excursion instead of at the beginning.

**Excursion C.5.**—Special attention is directed to the character of excursion C.5. The mode of travel by a specially chartered steamer on the Great Lakes, is in itself an attraction. Among the many points of interest may be mentioned, Niagara Falls, the magnificent scenery of the north shore of Lake Huron and the thousands of islands in Georgian Bay. The route traversed presents opportunities for the examination of a Palaeozoic section from the base of the Lowville (Ordovician) to the upper strata of the Devonian. Opportunities will be afforded for collecting fossils in certain localities of world-wide reputation for the profusion of their organic remains. More particularly may be mentioned, Port Colborne, wth its wonderful Onondaga coral reefs; the classic Hamilton localities near

Thedford where nearly 300 species occur; the extremely rich Richmond and Lorraine strata on the shore of Manitoulin island; and the Niagara beds near Manitowaning with an abundance of exquisitely preserved silicified corals.

Students of the pre-Cambrian will be interested in the original Huronian region of the north shore of Lake Huron and in the development of the Grenville series on Parry island.

At Wekwemikong on Grand Manitoulin island a characteristic native "show" is to be given by the Indians. In 1836, by treaty, Grand Manitoulin island was reserved for the various Indian tribes then occupying the islands and adjacent regions of Georgian Bay. The island was to be a haven for all homeless Indians and to-day numerous tribes are represented on Manitoulin.

**Excursion C.8.: Juneau—Yakutat Section.**—This section of the excursion will be under the guidance of Dr. Lawrence Martin, who has spent a number of years making a special study of the region

Five or six days will be devoted to this section of the C.8 excursion and this length of time should be amply sufficient.

Among other points of interest that will be seen and in many cases examined in detail, are: the Fairweather and St. Elias ranges, 4,878 to 5,487 metres high, covered by snowfields and glaciers including the La Perouse and Malaspina glaciers; the front of the great Piedmont ice sheet of Malaspina glacier, the tidal ice front of the Guyot lobe, the forest-covered terminus of the Marvine lobe; the eastern border of Malaspina glacier in Yakutat Bay; the shrub-covered ablation moraine upon Variegated glacier; streams depositing outwash gravels; the calving of icebergs; cirque vacated by a fallen glacier; beaches, sea cliffs, etc., uplifted 2 to 14.4 metres by earthquakes of 1899, fault scarps 1.3 to 2.4 metres high formed by same earthquakes; the Nunatak glacier, hanging valleys, till-veneered outwash gravels, tidal, land-ending and cascading glaciers, etc., in Russell fiord; moraine and glacio-fluvatile phenomena about the terminus of Hidden glacier (advanced 3.2 kilometres between 1906 and 1909); fiord with submerged hanging valleys, submarine moraines, buried forests; strand lines of former glacier lake; Glacier Bay and Muir glacier (receded over 14 kilometres, 1899 to 1911, vertical ablation of about 366 metres).

During the time devoted to this section of the C.8 excursion an opportunity will be afforded of inspecting the Treadwell mine, one of the largest and most important gold mines of the world.

It is possible that the itinerary of C.8 will be changed in so far that the Juneau—Yakutat portion of the excursion may precede the visit to Dawson.

**Special Dates.**

Sunday, July 13, Excursion A.1, Quebec and Maritime Provinces, leaves Montreal.

Wednesday, July 23, Excursion A.3, Sudbury-Cobalt-Porcupine (Ontario), leaves Montreal and Toronto.

Thursday, July 24, Excursion A.2, Haliburton-Bancroft (Ontario), leaves Montreal.

Friday, August 1, special day at Ottawa.

Saturday, August 2, special day at Montreal.

Thursday, August 7, opening day of session at Toronto.

Thursday, August 14, last day of session at Toronto, Excursions C.1 and C.2 start.

Tuesday, August 26, special day at Victoria, B.C.

# RAILWAY PRIVILEGES IN CANADA

**Special Arrangements for Professional Members.**

Professional members are defined as members of the Congress who are geologists, mining engineers, geographers and others engaged in the study or application of some branch of geology, (regulation 8a, Second Circular, page 7).

To professional members of the Congress and to dependent members of their families, a special form of certificate will be given. The possession of this certificate will enable the person to whom it is issued to purchase and use during a limited period of time railway tickets at a much reduced cost, to and from any point in Canada at the following rates and under the following conditions.

1. One way (or single tickets) at one-half the lowest one way first class fare.

2. Round trip (or return tickets) at lowest one way first class fare provided the same route is followed going and returning.

3. Circuit tours (or tours in which various points on different railways are visited) at one-half the lowest one way first class fare from point to point via route traversed.

4. Exceptions. There are a few small, privately owned railways and a few steamboat connections to which this plan does not apply but it is not considered necessary to detail them here. Particulars on application.

5. Dates of sale and limits of time of travel. Tickets may be used from June 15th to October 31st, 1913. Tickets cannot be used or purchased after October 31.

6. Stop overs (i.e., permission to break the journey and stay at any place on the route) will be allowed on application to conductor of train or purser of steamboat. It is necessary to make such application before getting off train or steamboat.

The certificate will be sent to the member's home address. If, however, applications for membership are received too late, the certificates can be obtained from the Secretary of the Congress who will meet the members on their arrival at Montreal before excursions A1, A2, and A3 start, or if they arrive at Vancouver or Victoria, certificates can be obtained from the passenger agents of the Canadian Pacific Railway at either of these places.

**Special Arrangements for Non-professional Members.**

A reduction of single fare plus 25 cents on certificate plan will be granted to all persons travelling directly to and from the sessional meeting at Toronto. Persons attending should purchase one-way first-class full fare tickets (fare for which must not be less than 50 cents) to place of meeting, and secure a certificate to that effect on the standard certificate form.

These certificates must be validated at the meeting and should be presented for that purpose at the secretary's office, University of Toronto, not later than August 12th.

A special agent of the transportation companies will attend the meeting on August 8, 9, 11 and 12, for the purpose of validating the certificates and at that time will collect the 25 cents referred to above. Certificates may then be exchanged for tickets for the return journey without further charge.

Certificates issued at points in Canada, Fort William, Ontario, and east, in connection with tickets good going August 3 to 9, inclusive, will be honoured for tickets for the return journey until October 31, 1913.

Certificates issued at points in Canada west of Fort William, Ontario, in Ontario, Manitoba, Saskatchewan, and Alberta, in connection with tickets good going July 31 to August 5 inclusive, will be honoured for tickets for the return trip until October 31, 1913.

Further information may be obtained from any ticket agent in Canada or from the secretary.

## RAILWAY PRIVILEGES IN UNITED STATES

**Special Rates to Members Attending Congress from Certain Points on Pacific Coast in the United States.**

Tickets from certain points in California to Toronto and return, may be purchased on certain dates at a reduced rate of $95.70. Such tickets are valid for transportation eastbound for fifteen days from date of sale and are valid for transportation westbound for three months from date of sale, but not beyond October 31, 1913.

Similar tickets will be sold daily from May 28th to September 30th inclusive, at reduced rate of $92.00 from certain points in Washington and Oregon; tickets from this territory will also be valid for transportation eastbound for fifteen days from date of sale, and for return trip not later than October 31st, 1913.

Regular nine months tourist tickets, approximating about one fare and one third for the round trip, are in effect daily from certain points in the States of California, Nevada, Oregon and Washington to Toronto and other Eastern points.

Further information regarding dates of sale, etc., may be obtained from local ticket agents in States named.

# LUCKY JIM ZINC MINES, LIMITED

Prior to holding the annual meeting of the Lucky Jim Zinc Mines, Limited, at Kaslo, B.C., on May 1st, the directors issued to the shareholders the following statement of the operations of the company since the last annual meeting:

The operations at the mine, which were being carried on by way of development work in the lower levels, were continued and preparations were made for shipping clean ore as soon as transportation facilities, being provided by the Canadian Pacific Railway Co., were ready. The railway was completed to the mine about August 1st. Prior to that date orebins were constructed at the mine, for shipping purposes, these bins having a capacity of about 150 tons. An aerial tramway, about 600 feet in length, was also constructed, to convey the ore from the portal of No. 5 tunnel to the loading bin above the railway track.

A body of shipping ore of considerable size had been developed in No. 5 tunnel, so, as soon as the railway became available, ore was stoped from between Nos. 5 and 4 levels, and shipment was begun. During the months of August, September, October, and November, about 1,850 tons of ore was stoped and shipped to the smeltery at Depue, Illinois. This practically exhausted the shipping ore from that stope. During the time that stoping was being done, development work was continued in No. 6 level on a likely-looking vein that had been discovered earlier in the year. A small amount of shipping ore was obtained from this vein, but the larger portion of the ore was unsuitable for shipping without concentration.

It has become evident to our engineer and mining superintendent that the vein discovered in No. 6 level is a continuation of the orebody stoped in No. 5 level, and development work has since been done to prove that this is so. While results have been satisfactory, no large body of shipping ore has been opened by this work.

In December, seven or eight more cars of ore was mined and shipped and then heavy snowslides occurred and completely tied up the transportation facilities. The railway company was unable to get the track clear of snow before the middle of March, since which time ore-shipping has been resumed. Present prospects are that the company will be able to mine and ship seven to ten cars of shipping ore per month.

The quantity of ore shipped between August 1 and March 31 was 2,090 tons, gross, and the gross receipts from the smeltery on account of this ore were $77,537. The freight paid thereon was $22,608, and the duty $19,185; together $41,793. This left $35,744 as the amount of net cash received from the sale of 2,090 tons of ore. The figures are subject to slight adjustments in regard to freight and duty, but the difference one way or another will be but small. The average net value of the ore was $17 a ton, which is a high average.

The proceeds received have been applied partly to pay a claim of the smeltery company against this company of about $17,000, which amount, after having been owing more than two years the smeltery company required to be paid. The remainder of the money was used in paying wages and for supplies. On account of there having had to be handled a large quantity of concentrating ore and waste material, receipts were insufficient to pay for all the requirements of the mining done.

Your directors have been obliged to sell part of the treasury stock, in order to raise money to carry on mining operations and to meet other requirements. The company still has available for sale about 150,000 shares of treasury stock, of this the Canadian Pacific Railway Co. holds 100,000 shares as security for a contract made with that company by the former management of the Lucky Jim Co., for the shipping of ore to the smeltery over the railway company's lines.

Your directors found in existence a smelting contract with the Empire Zinc Co., of Denver, Colorado, which so far it has seemed desirable to maintain. During the past year the smeltery company has given every satisfaction by the manner in which it has handled the Lucky Jim ore.

At the present time there is not available in the mine any large body of shipping ore developed. There is, though, some 50,000 tons of concentrating ore, but it will not be possible to realize on this until after a mill shall have been provided for concentrating it. There is not available in British Columbia a suitable custom mill to which the company could send its concentrating ore, so it will be necessary to build one. Our mine superintendent's estimate of the value of the above-mentioned concentrating ore is $214,000 net, that is, after payment of all costs of mining, concentrating, freight and duty. The cost of a concentrating mill with a capacity of about 100 tons a day would be about $80,000, which sum would also include the cost of providing the additional power necessary to operate the mill.

The concentrating ore mentioned is partly broken down in the mine, so the quantity can be estimated with near approach to certainty. In addition, there is reasonable expectation of a much larger amount of concentrating material being developed in the future.

It is evident that, by some means, a concentrating mill must be provided at the earliest possible time, in order to secure the profitable operation of the mine. The means to be adopted for its provision is one of the important questions to be considered by the shareholders.

During the past winter the directors found it necessary to instal a steam plant to operate the compressor and electric light plant for the property. This was done at a cost of about $4,000, and the plant is working satisfactorily. With the opening of spring, the water supply will again be available so that, with the steam power as well, the company will have ample power for all purposes required until a concentrator shall be put in.

The directors invite the co-operation of shareholders in connection with the further development of the property. They are of opinion that, with a concentrator built at or near the mine, the operation of the property will result very profitably, and that with sufficient development much larger quantities of ore will be found. They are informed that the quality of the ore in the Lucky Jim mine is unique in America, as regards both clean and concentrating ore. With a concentrator provided, they look for a bright future for the property.
